Takao Kato**

June 2006

Abstract

To investigate the size and the timing of the direct impact of participatory arrangements on business performance, we assemble and analyze extraordinary daily data-- for rejection, production and downtime rates for all operators in a single plant during a 35 month period, more than 77,000 observations. We find that: (i) membership in offline teams initially enhances individual productivity by about 3% and lowers rejection rates by about 27%; (ii) these improvements are dissipated, typically at 10 to 16% per 100 days in a team; (iii) while initially teams lead to more downtime, these costs diminish over time; (iv) the performance-enhancing effects of team membership are generally greater and more long-lasting for team members who are solicited by management; similar relationships exist for more educated team members. Findings are consistent with core hypotheses that employee involvement enhances productivity and quality through mechanisms including employees becoming better motivated, more informed and paying greater attention to product details. Findings also square with diverse hypotheses concerning management solicitation and education but are inconsistent with hypotheses based on Hawthorne effects.

The Impact of Teams on Output, Quality and Downtime: An Empirical Analysis Using Individual Panel Data

I. Introduction

In many areas of economics the gains from advances in econometric techniques and theory have been muted because of limited data (Griliches, 1994:2). This proposition applies especially forcefully in the literature concerning the nature and effects of human resource policies. While much theoretical work points to the existence of powerful links between business performance and workplace innovations, especially high performance workplace practices (HPWPs) such as employee involvement and incentive pay, often theorists disagree over the size, direction and nature of such links.¹ Moreover, in attempting to assess recent theoretical advances in this area, most empirical work necessarily has used data from national surveys of firms or establishments from diverse industries (e.g. on firm-level outcomes see Craig and Pencavel, 1995; Appelbaum and Batt, 1994; Jones and Kato, 1995; Freeman, Kleiner and Ostroff, 2000.)² Unfortunately, while such studies are very valuable, potentially national cross-industry studies have significant limitations including measurement problems, endogeneity, and omitted variables (e.g. Bartel, Ichniowski and Shaw, 2004).

One important response to these difficulties of national cross-industry studies has been “insider econometric studies” in which researchers conduct detailed qualitative field research at establishments within a narrowly defined industry and develop detailed understanding of the actual production process and the use of HPWPs. Researchers then obtain access to unique internal and confidential data at the level of establishments or branches (e.g., physical

¹Compare, for example, Alchian and Demsetz (1972), with Holmstrom and Milgrom, 1995. See also for example Kandel and Lazear (1992), Gibbons (1997) and Prendergast (1999) who provide insightful surveys of the theoretical literature.

²On establishment-level outcomes see for example Black and Lynch (2001) and Cappelli and Neumark (2001). Most international studies are also of this type. For instance, see Kato and Morishima (2002) for Japan; Addison and Belfield (2000), Freeman and Conyon (2001), DeVaro (2004) for the U.K.; Caroli and Van Reenen (2001) for France; Eriksson (2003) for Denmark; Bayo-Moriones, Galilea-

productivity, rejection rate and downtime at the establishment-level) and estimate the impact on establishment performance of HPWPs (e.g., Ichniowski, Shaw and Prenzushi, 1997).³

Another important development is empirical work by economists that uses *data on individual workers* employed by a *single firm* (e.g. Hamilton, Nickerson and Owan, 2003; Lazear, 2000).⁴ These “econometric case studies” allow one to incorporate more detailed information on key features of the organization of production than is possible using traditional data for a large number of firms. Thus they go deep within the “black-box” of the firm and enable one to obtain more precise estimates of the effects of HPWPs on firms and employees and the channels through which these practices operate. However, since such data are notoriously difficult to obtain there have only been a handful of such “insider econometric” studies. It is to this latter class of work that this paper makes several contributions.

Specifically, we provide the first rigorous empirical analysis of the economic effects of employee involvement in teams in a plant that had only recently introduced *offline* teams and where not all workers were team members. We make use of a unique data set that has been constructed for this case during a period of thirty-five months. Our data are for *all* operators in that plant during that period and include all workers who remain in the plant as well as workers who leave the firm. For these operators we have *daily* observations for key measures of *individual* performance, specifically measures of individual *physical production* and rejection rates for individual worker output. Also we are able to use data on individual rates of downtime. These data enable us to meet the demanding data requirements that are required by institutionally

Salvatierra, Merino-Díaz de Cerio ((2003) for Spain; Leoni, et al. (2003) for Italy; and Zwick (2004) for Germany.

⁴ Pioneering works using internal personnel data in economic research include Medoff and Abraham (1980), and Baker, Gibbs, and Holmstrom (1994a, 1994b).

informed econometric case studies. These extraordinary data enable us to provide rigorous empirical tests of diverse hypotheses including the direct impact of membership in offline teams on production and quality.

Our interest in teams in part reflects the changing nature of workplaces during the last thirty years or so. A notable feature is the emergence of HPWPs including mechanisms that provide for employee involvement (e.g. teams, quality circles, total quality management, and information sharing) and incentive pay (e.g. profit sharing and employee stock ownership).⁵ Particular attention has been paid to the use of various kinds of teams. While estimates of the incidence of teams vary, there is agreement that there has been a dramatic increase in the use of employee involvement through mechanisms including teams in US industry. The structure of the paper is as follows.

In the next section we briefly provide a conceptual review and develop the hypotheses we will test in our empirical work. This is followed by a review of relevant econometric case study evidence. To provide adequate institutional context for our statistical analysis, we then provide a detailed discussion of key institutional features for our case. In the same section we also discuss our data and provide descriptive statistics for key variables used in the empirical work. The main parts of our paper are contained in the penultimate section where we present our empirical strategy and findings.

A key finding is that membership in offline teams results in modest but nevertheless significant enhanced individual rates of output. More dramatic effects are found for product quality as improved quality control leads to large falls in rejection rates. Evidence is also found that the introduction of teams is initially accompanied by significant costs in the form of

⁵ For estimates of the incidence of teams in the U.S., based on establishment-level surveys, see for example Osterman (1994), and Black and Lynch (2004). For estimates of the team incidence based on firm-level surveys in the U.S., see for example Freeman, Kleiner and Ostroff (2000). For estimates based on worker surveys in the U.S., see for example Freeman and Rogers (1999).

increased rates of downtime, though these costs dissipate over time. All of our findings are insensitive to including/excluding operators who left during the study period. Consistent with theorists who stress the benefits of complementarities in organizational design, we find that the impact of enhanced employee involvement through teams alone is not sustained at initial levels.

Our data also enable us to investigate issues concerning the team member selection process and the possible complementary role of education in team effects. When we examine team effects separately for those solicited by management and those who volunteered to become team members without management solicitation, we find that the performance-enhancing effects of team membership tend to be greater and more long-lasting for solicited team members and that the cost (or increased downtime) of team membership is smaller and diminishes more quickly for solicited team members. The finding is consistent with our conjectures: (i) that management will have a better sense of those individuals who will likely be better fits as a team members and also which individuals are more likely to continue to get motivated and to learn skills in teams; (ii) that some of those employees who volunteer to become team members without management solicitation may be behaving opportunistically; and (iii) that management solicitation serves as a credible signal to the solicited workers that they are indeed in the promotion tournament for line supervisors. Turning to education, when we study whether the performance effects of team membership differ between those with and without education beyond high school, we find that the performance-enhancing effects of teams (especially quality improvement) are generally greater and more long-lasting for team members with education beyond high school. This evidence suggests a complementarity between teams and formal education.

II. Conceptual Framework and Hypotheses

In this section we briefly review key aspects of the theoretical debate as it relates to the expected association between employee involvement and ultimately firm performance. Where

possible, we review literature that focuses on employee participation specifically via membership in teams. Since ours is not a theoretical contribution and good reviews of this literature already exist,⁶ here we merely provide summary overviews of some of the key elements in the debates. Before highlighting some of those themes, however, we make two observations.

First, we recognize that the theoretical literature sometimes does not clearly recognize that, in the real world of work, teams may assume various organizational forms. For the most part, theorists implicitly appear to assume that teams are *on*-line (such as “cells” in many US companies) and not of an *off*-line character (such as, in many U.S. firms, cross-functional project teams, task forces, committees and problem solving groups or shop floor committees and joint labor-management committees in Japan or works councils in Germany.)⁷ Second, in tracing the possible links between *individual* participation in a “team” and ultimately with firm performance, we recognize that this is an extraordinarily complex process. In examining those relationship important theoretical contributions have been made by a range of social sciences other than economics, and including social psychology and sociology. Notions of intrinsic rewards (e.g. Benabou and Tirole, 2003), organizational commitment and trust must share the stage with assumptions of individual and bounded rationality.

Our central concern is with the impact of employee involvement through teams on business performance. As already indicated, there is disagreement amongst theorists both as to the expected impact of organizational innovations such as teams on individual, group and ultimately firm performance as well as concerning the main drivers in these relationships. For those who see teams as having largely beneficial effects for firms (and possibly workers), it is often argued that teams are required because of other developments, notably the remarkable changes in information and communication technologies and the intensification of competition in

⁶ See for example Gibbons (1997), Gibbons and Waldman (1999), and Prendergast (1999).

⁷ For discussions of various participatory arrangements in Japan see Kato (2003).

product markets that increasingly are globalized. These changes mean that firms are, amongst other things, better able to manage inventory and, in turn, suggest that there will be bigger payoffs to complementary changes in work organization and quality practices. In particular it is expected that there will be benefits to firms to encourage and reward programs that facilitate more horizontal co-ordination (Milgrom and Roberts, 1995) among workers and produce improved communications among workers so that they can better solve problems.⁸ In this view, as the extent of horizontal co-ordination grows, this produces a need for structural changes within organizations that provide even greater opportunities for enhanced participation, such as teams and financial incentive systems that better link enterprise performance with the involvement of broader groups of workers than just top managers.

While such arrangements are expected to produce several beneficial outcomes we might broadly group them into two sets. First is the *direct* impact of teams resulting from improved motivation and enhanced discretionary effort by team members and enhanced skill and knowledge of team members. By participating in teams, team members suffer less from information asymmetry, and develop more trust in management, stronger commitment to the organization and their goals are more aligned with the firm's. The result is improved motivation and enhanced discretionary effort among team members. Moreover, team members engage in knowledge sharing among themselves, and enhance their human capital. Improved performance of team members results. The other set of effects are the indirect or *spillover* effects of teams. Teams may improve not only team members' performance but also non-team members' performance. These result mainly from two sources. First, by solving various work problems, teams may contribute to the overall efficiency of the workplace and thus both team members and non-team members working in the same workplace end up improving their performance.

⁸ Note that this view stands in sharp contrast to arrangements in the traditional vertically organized firm (as modeled by theorists such as Alchian and Demsetz, 1972).

Second, team members, whose goals are more aligned with firms' objectives, may engage in horizontal or peer monitoring. As a result, non-team members are less likely to shirk and thus their performance also improves.

We further expect improved performance as a result of teams to be felt more strongly in product quality than in productivity.⁹ Arguably the introduction of participatory arrangements in general or offline teams in particular might be expected to change employee attitudes so that team members better understand the crucial importance of quality for organizational success.¹⁰ Or the introduction of membership in teams is apt to foster and enhance trust which has been identified as a key component of successful business systems (see, e.g., Ben-Ner and Putterman, 2003). In turn this might be expected to lead to discernible differences in the quality of the care and attention that team participants devote to their jobs. Ultimately these changes might produce improvements in quality control.

The principal argument made by those who are more pessimistic as to the impact of teams upon firm performance is that the existence of teams may result in free riding by some team members (Alchian and Demsetz, 1972). While this point is deserving of careful attention in many circumstances, arguably the force of the argument is apt to be undermined in situations when workers participate in cross-functional off-line teams rather than on-line teams. Furthermore, in most business organizations, the economic game is repeated. In such circumstances, to the extent that peer monitoring is a potent consideration, there are strong incentives for all team members to engage in peer monitoring.

Consequently the first hypothesis we examine is whether the introduction of offline teams leads to behavioral changes (such as workers becoming more motivated, better informed and more apt to share knowledge) and, in turn, whether this produces measurable differences in, for

⁹ A similar hypothesis was developed for call center workers by Batt (1999).

example, discretionary effort and thus individual production. A second and related hypothesis is whether this organizational innovation produces employees who better understand the crucial importance of quality for organizational success. In turn does this lead to discernible differences in the quality of the care and attention that individuals devote to their jobs, ultimately producing improvements in quality control?

While the bulk of the theoretical literature focuses on issues concerning the impact of teams on productivity and product quality, there are other important themes in the literature. Of key interest to some is the recognition that the introduction of various forms of participation, even if accompanied by overall improvements in organizational effectiveness, may also result in major costs to the organization. In other words, there is a need to consider participation as an investment (Levine and Tyson, 1990.) In the case of offline teams, the key costs are the opportunity costs incurred when team members attend team meetings during regular hours.¹¹ It is important to investigate hypotheses that bear on the extent and the time profile of these costs. For example, is it the case that the introduction of teams leads to opportunistic behavior by team members (who do not forego compensation when attending meetings)? Does the extent of downtime grow over time (as teams become a vehicle for more opportunistic behavior by team members)? Or is it the case that team members do not engage in such opportunistic activities and that they become more efficient at conducting and implementing team business over time? These hypotheses relating to the time profile of organizational costs as reflected in downtime constitute our third set of hypotheses. Following Levine and Tyson (1990) we hypothesize that the introduction of participatory practices must be viewed as an investment by the firm and that

¹⁰ Many offline problem-solving teams, such as QC circles are created specifically to solve product quality problems.

¹¹ Though offline teams in Japanese firms (such as celebrated QC circles) traditionally meet after regular hours with only limited or no compensation, offline teams in U.S. firms normally meet during regular hours. Thus the opportunity costs of offline teams are particularly important for U.S. firms. See Kato (2003) for offline teams in Japanese firms.

this organizational innovation is expected to be accompanied by some initial set-up and learning costs. But our expectation is that these costs will be dissipated over time if teams function well.

The fourth set of hypotheses to be tested concern the time profile of the impact of teams on business performance. Some theoretical and empirical literature suggests that an individual change in organizational design is expected to be sufficient to produce *sustained* benefits to the firm.¹² By contrast other literature argues that usually what is needed for sustained benefits to the firm are *complementary* measures and that an individual initiative when introduced alone may be insufficient to lead to persistent gains. For example, employees might need more sharing of enterprise rewards through financial participation, such as profit sharing, gainsharing and employee stock ownership to accompany teams lest their commitment to teams becomes undermined (Milgrom and Roberts, 1995, Ben-Ner and Jones, 1995 and Kato and Morishima, 2002). The QC circle literature often reports that the productivity-enhancing effects of QC circles introduced by U.S. firms in 1980s has proved to be short-lived since QCs lacked a complementary mechanism to delegate power to front-line workers (e.g., Lawler III, 1986, Griffin, 1988, Kochan and Osterman, 1994, Levine, 1995).

An alternative explanation of the short-lived nature of the productivity effect of teams is that it is a Hawthorne effect.¹³ According to this line of reasoning, team members regard themselves as special or they receive individual attention from management. Consequently, better performance does not flow from team membership per se, but rather from the special feelings felt by team members who are given unusual attention. However, such novelty tends to wear away over time and thus the performance improvement is expected to be short-lived.

Some employees become team members after solicitation by management while some volunteer to become team members without management encouragement. The next hypothesis

¹² See for example reviews in Blinder (1990) and in Blair and Kochan (2000).

¹³ See, for instance, Batt (1999) for a discussion of Hawthorne effects and teams.

concerns a possible difference in team effects between solicited and unsolicited members. Specifically we hypothesize that the performance-enhancing effects of team membership will be greater, and perhaps more importantly, more long-lasting for solicited members than for unsolicited members. Moreover, the cost of team membership (increased downtime) will be smaller and diminish more rapidly as team members engage in learning by doing. One conjecture is that this difference may arise in part because, compared to individual employees, skilful personnel managers will have a better sense of those individuals who will likely be better fits as team members and also which individuals are more likely to continue to get motivated and to learn useful skills in teams. Second, it is possible that some employees who volunteer to become team members with no management encouragement may be behaving opportunistically—they are simply seeking a paid break from their daily production work, provided that they are paid hourly and not by piece rate. This line of reasoning also suggests that the performance-enhancing effects of team membership may be smaller and short-lived for such unsolicited and volunteered team members than for solicited members. Third, it is also possible that management solicitation serves as a credible signal to the solicited workers that management considers them in the viable pool of candidates to become line supervisors (or in the promotion tournament). Having been convinced that they are in the promotion tournament, they will be motivated to work harder to win the tournament. Thus the performance-enhancing effect of team membership will be greater and more long-lasting for solicited members than for unsolicited members.

Relatedly, the aforementioned Hawthorne effect may be particularly relevant for solicited members. Specifically, it is likely to be solicited team members (rather than volunteers) who consider themselves special or who receive particular attention from management. Thus, the existence of a Hawthorne effect would also point to a greater initial improvement in performance after the start of team membership for solicited members than for other members. However,

since the literature also suggests that the Hawthorne effect should wear away over time, this implies that the performance-enhancing effect of team membership for solicited members is expected to be particularly short-lived. Hence, if it is a Hawthorne effect that is driving enhanced performance by solicited team members, the time profile of the performance improvements is predicted to be quite different compared to the pattern that is consistent with the first three hypotheses discussed previously.

The last hypothesis concerns the relationship between the performance effects of team membership and the level of education. It is plausible that team members with more education learn skills more effectively in teams and hence enjoy higher performance gains from team membership. Furthermore, such educated team members may continue to find ways to utilize those skills in their daily work. Simply put, education and teams may be complementary. The potential importance of such complementarity has been suggested in the literature yet there is very little systematic evidence on it.¹⁴

III. Previous Empirical Work

As already indicated there is an enormous amount of previous empirical work by economists in this broad area and especially as it concerns our first hypothesis on the impact of “participation” upon business performance. However, for the most part the empirical economics literature has not used data that provides *direct* evidence on the impact of participatory practices such as teams on the behavior of *individual* workers and then by extension to the impact on organizational and ultimately enterprise performance. Instead, in part because of the difficulties in obtaining adequate economic data for individuals, studies have used data at higher levels of

¹⁴ For example, Ichniowski, Shaw and Prennushi (1997) find evidence for formal off-the-job training as an important ingredient of the high performance work system. Our study complements their work by testing more directly whether improvement in individual worker performance as a result of team membership is greater for more highly educated workers.

aggregation—mainly at the level of the firm, though increasingly at the plant level. In these studies, if links between, for example, enhanced business performance and “participation” have been identified then these have been ascribed to the influence of the existence of a particular participatory practice on individual behavior. However, such ascription does involve a leap of faith—the available evidence on the posited link between individual behavior and firm performance remains largely indirect.

Similarly, the need to use data at the firm or establishment level has meant that testing of hypotheses that relate to the expected timing of the impact of participation, or to the effect of differences in individual worker characteristics, largely have been unable to be undertaken. Also, the literature has tended to focus on the impact of participation on outcomes that are comparable across firms, such as value added (rather than production) and much less attention has been devoted to the impact of participation on outcomes such as quality.¹⁵

There are, however, a handful of studies that do make important steps in beginning to provide direct evidence on hypothesized links between HPWPs such as teams and individual behavior. A number of pioneering studies (e.g. Lazear, 2000, Kleiner and Helper, 2003, Fernie and Metcalf, 1999, Paarsh and Shearer, 1999, and Knez and Simester, 2001), focus on the effects on individual worker performance of the switch from time rates to piece rates or to performance pay. A related line of work examines the effects on individual worker performance of the shift to team production (e.g. Batt, 1999 and Hamilton, Nickerson and Owan, 2002).¹⁶

The research of Hamilton, Nickerson and Owan (2002) is probably the closest to our study. They use panel data for a textile plant to empirically examine worker productivity and participation as the plant gradually moved to a team production system. They find among other

¹⁵ An important exception is Ichniowski, Shaw and Prennushi (1997) who use plant-level data on productivity and product quality.

¹⁶ Nagin, *et al.* (2002) examines the impact on opportunistic behavior of call center employees of exogenously introduced variation in monitoring.

things that the adoption of *on-line* teams at the plant improved worker productivity by 14% on average. Our study differs from theirs in three important ways.¹⁷ First, we examine the impact of *offline* team membership as opposed to *online* team membership. In this sense, both studies are complementary. Second, we use not only a productivity measure but also two additional performance measures, including the product rejection rate, which is an objective measure of quality, and downtime. Third, data on worker characteristics allow us to test additional hypotheses, notably whether the performance effects of team membership are greater for team members with more formal schooling and team members who were sought after by management.

IV. The Case, Data and Descriptive Statistics

The case we investigate is located in central New York in one of the four counties of Oneida, Onondaga, Herkimer and Madison that are close to our home institutions. While the population of the average U.S. county grew by 35% during the period 1969-1999, these counties have either flat or falling populations, and in the case of Oneida county, population fell by more than 15%. These counties are more homogeneous than is the norm in the U.S. despite a decade or so of modest rates of immigration from countries including Bosnia, Russia and Viet-Nam. Two of the four counties are more than 96% white, compared to a U.S. average of about 75%. While the proportion of high school graduates tends to slightly exceed the national average, the percentage of college graduates typically is below the national average.

¹⁷ There is, however, an important methodological implication of this difference in the type of teams. Once individuals become online team members, individual performance data may no longer be available and instead may have to be replaced with aggregate team performance data (as in Hamilton, Nickerson and Owan, 2002). By contrast, in our study, the available performance data do not change before and after individuals become offline team members. By continuing to have access to individual daily performance data we believe we are using those data that are most pertinent for rigorous hypothesis testing of the impact of membership in offline teams.

The postwar period has witnessed only limited success in maintaining highly paid manufacturing jobs in the region. Partly as a consequence, average wages and salaries in the counties (in 1998 dollars) were about the same or lower in 1998 than in 1969, in contrast to U.S. counties in general in which these disbursements rose over this period.

Our case, hereafter PARTS, is a privately owned, non-unionized subsidiary of a multinational firm. At the end of November 2001 PARTS employed 225 employees, including 134 operators who were directly involved with production. PARTS is a single-plant firm (as opposed to a multi-plant firm), and all 134 operators work in the same plant. PARTS has grown rapidly from 30 workers in 1988 and real sales have tripled since 1995. However the industry is very competitive and profit margins are thin.

PARTS is a light manufacturing firm that makes a range of small components mainly to be used by larger manufacturers.¹⁸ Typically production items are produced in large runs. While products would not be classified as “hi tech” customers demand high quality in the parts that they buy and, for example, specify very low tolerances in crucial parts of the components that PARTS manufactures. These parts are produced by different machines that require different though typically not very high levels of skill to operate. While the nature of the technology sets limits to rates of production, the machines permit large discretion in tasks performed by operators so that there is much larger scope for variation in the quality of the product produced by different operators who use the same machine.

During the study period, hourly workers typically started at \$6, though normally within a year they were earning \$7.50 an hour. During the decade preceding our study this firm had never laid off employees although occasionally the firm had dispatched workers on a fixed term basis (6 months) to neighboring firms.

¹⁸ Our confidentiality agreement with PARTS prohibits us from identifying the specific product they produce.

Of key interest to us in choosing this case was the fact that, until recently, the human resource (HR) practices at this non-unionized firm were similar to many firms in the U.S. insofar as “high performance workplaces practices” were essentially absent. But, as in many U.S. firms, that situation changed when teams were introduced. In other words we believe that PARTS may be representative of many US firms whose HR practices are undergoing this kind of change.

Teams were started at PARTS in June 1999 after the introduction of teams by the parent firm. The CEO appears to have taken the introduction of teams seriously, reflecting in part his personal interest in employee empowerment. For example, to help to introduce teams to PARTS, he hired a full-time consultant with long experience in the introduction of teams at other firms (the consultant continues to work for PARTS). There are two types of teams, A-teams and B-teams. A-teams are cross-functional and each A-team consists of on average of eight team members including one engineer. Importantly for our analysis the way teams were introduced means that not all workers were members of A teams. B-teams are quite different from A teams. B teams consist of only managers and supervisors and their main function is to decide whether to approve suggestions made by A-teams. Teams work on specific themes (we will provide some examples of team projects below) and meet on average for 30 to 45 minutes a week during regular hours. Participation in teams is in principle voluntary although management sometimes solicits certain workers to become team members (we will discuss this in more detail later as well). There is no compensation for team participation, although team participation is evaluated as an important part of the annual performance evaluation process.

The centrality of teams in the evolving system of human resource management practices at PARTS is perhaps indicated by the relatively limited development of other “high performance workplace practices.” Thus while all-employee meetings are held each month (in fact on pay day, the second Thursday of every month), the meetings last only 30 minutes and there are rarely questions and answers and confidential information is not shared. In addition, financial

participation by non-managerial employees at this case is quite limited. There is, for example, no plan providing for profit sharing or employee ownership. However, during the last four years the firm has been contributing \$500 each year to each employee's 401K plan as a discretionary bonus. Employees seem to expect to receive this bonus unless the firm has a particularly bad year. Neither management nor labor considers it a profit sharing plan.

In order to help us to gain a detailed knowledge of the nature of production and the realities of key dimensions of labor relations at the plant, several types of data were gathered. In this process, special attention was paid to the nature and functioning of offline teams. During an initial, preparatory stage, lengthy interviews with diverse personnel, notably managerial personnel, were conducted. Also a questionnaire was completed that used responses from the principal HR manager. Finally, worker shadowing exercises were conducted over periods of one to three months.

These data sources provide much suggestive anecdotal information that, in general, team members viewed teams in a positive light. Thus during our worker-shadowing one worker attested: " Recommendations made by teams affect our work at least to some extent and plans are very likely to be carried out". At the same time we heard claims that while teams may initially have had favorable impacts, over time these benefits were believed to have lessened. In other words, with the passage of time, in the absence of tangible rewards, the interest of employees in being cooperative and their levels of loyalty appear to have fallen. In addition, the CEO told us that he was clearly aware of the falling enthusiasm among team members and that this has prompted him to start considering the introduction of a plant-wide gainsharing plan.

We also observed several examples of projects that offline teams at PARTS had suggested and which have been implemented. For example, the shipping area (about 400 square feet) was originally quite disorganized and access to the shipping area was cumbersome at best. A team reorganized this shipping area and thereby created additional free space equaling 175 square feet.

In turn this allowed workers at all stations to access the shipping area quickly and smoothly. Another example is the development of a new labeling system for their spare parts which reduced the time required for labeling by half and reduced product defect caused by the use of wrong parts. Other examples include developing a better fume extraction system at the wire solder station, revising onsite manuals and also devising better ways of posting these manuals, and a variety of ways of rearranging machine locations.

To provide more systematic information on the potential impact of teams on worker attitudes and behaviors (and thus potentially on outcomes for firms), we also undertook an unusual face-to-face survey of workers in March 2001. For this survey we received a very high response rate (close to 90 percent). Since findings from that study are discussed in detail elsewhere, here we summarize some of the major findings that emerge from that survey.¹⁹ Relative to non-team members, team participants consider themselves to be more empowered, sensed that more information was being shared by management, communicated more often with managers and supervisors within their work groups or teams, and communicated more often with workers outside of their work groups or teams. In addition the survey findings indicate that participants in teams put more effort into their work. The evidence is equally suggestive that attitudes and thus potentially the behavior of team members was being affected in other ways. Thus we find some evidence for participants displaying stronger organizational commitment and more trust towards management. In addition we note that team members are more satisfied with their jobs, are more positive about the use and contributions of their knowledge and skills and that there is no difference between team members and other workers concerning views on job stress.

¹⁹ See Jones, Kato and Weinberg (2003).

In sum the data based on interviews with HR officials, worker-shadowing, and surveys of individual employees together present a reasonably consistent story suggesting that the introduction of and membership in offline teams has been producing behavioral change in team members. However, there were also some indications that there were some interesting dynamics at work concerning the impact of these developments on individual behaviors. Finally, these data provide reasonably strong evidence of change in many of those areas that several theorists have long stressed, including trust, commitment and discretionary effort.

To provide compelling evidence, however, that teams do lead to actual changes in measurable outcomes such as production it is necessary to be able to test such hypotheses using appropriate and detailed economic data. In this respect we are most fortunate insofar as we have been able to collect records for individual workers on various aspects of their daily performance. Specifically we were able to obtain two sets of data for all 134 operators who were employed by PARTS as of November 30, 2001. First, for each of these 134 operators, we were able to collect daily performance data during the 35-month period, starting on January 1, 1999 and ending on November 30, 2001. These daily performance data are then matched with personnel records containing information on worker characteristics, including date of hire and education. These records also indicate whether or not individual workers were team members at some point during the period of data collection, and if so, whether they were volunteers or solicited by management. Hence we end up with a very large rich and unusually reliable micro data set.²⁰

Table 1 reports descriptive statistics for operators. The average operator is 39 years old with 3.8 years of tenure with PARTS, and his/her wage is quite low (\$7.64 an hour). The bulk

²⁰ We also have daily performance data for those operators who worked during part of this period yet were no longer employed by PARTS on November 30, 2001. Unfortunately, PARTS did not keep personnel records on these workers and hence we know very little about their worker characteristics (most importantly their dates of hire). However, when possible, we will use the daily performance data for those “job leavers” to check the robustness of our results.

of operators (62%) are female and 33% have education beyond high school (yet virtually nobody has a 4-year college degree).²¹ To see if team members differ systematically from non-team members in terms of some key worker characteristics, we also report descriptive statistics according to team status. First, from the table we see that 54 operators joined teams during the sample period. Reassuringly in most respects the characteristics of team participants and those who were never in teams are quite similar.²² The only exception is gender, with team members much more apt to be female. In short, except for gender, there is no evidence to suggest systematic bias in team participation in terms of observable worker characteristics.

Data were collected for three key measures of individual performance. The first measure is EFFICIENCY which expresses individual production as a percentage of a “norm” that is set for each machine (and which remained unchanged during the sample period.) Since most machines have an automatic counter that records each workers’ output each day, these data are extraordinarily reliable. The set of EFFICIENCY numbers for a worker during a year is used in the annual evaluation of each worker’s performance by his supervisor.

The second performance measure is the REJECTION RATE. This is a measure of quality and records the amount of defective production produced by an individual as a percentage of that individual’s production. To compile these data each production worker’s output is tested randomly (on average every other day.) Thus the REJECTION RATE is recorded for each worker for each audit day. Again these data are most unusual and are apt to be characterized by very tiny measurement errors. These sets of rejection rate data, as gathered during a year for each individual, are also used as part of the annual evaluation process of each worker’s performance by her supervisor.

²¹ Unfortunately data on education are missing for 31 workers.

²² Note that in many respects the workers in the firm are quite homogeneous. In addition there are no sharp differences in race and nationality. In such circumstances we expect that “social connectedness”

The third performance measure is individual DOWNTIME. This measures downtime hours for each individual for each day and includes all time not spent in production. This includes time spent setting up a station, time spent waiting for parts, machine repair, greasing, various meetings (including team meetings), training, cleaning up time, and time spent on any other breaks (including for illness and snacks.) Again these data are collected for each individual for each day.

Data for the three measures are shown in Table 2. Average EFFICIENCY, REJECTION RATE, DOWNTIME for all workers are, respectively 83.487%, 0.561%, and 0.890 hours per day. The rest of Table 2 presents average EFFICIENCY, REJECTION RATE, and DOWNTIME before and after individual workers become team members.²³ The data reveal that for all team members average EFFICIENCY is higher after joining a team (84.955 vs. 78.643%) representing an average 6.312 percentage-point improvement in productivity. Turning to the data on the REJECTION RATE we see that the average REJECTION RATE is considerably lower for team members (0.399 vs. 0.814%). This represents an average 0.415 percentage-point improvement in this measure of quality after workers became team members. Finally, when we look at DOWNTIME we see that average DOWNTIME is higher after workers joined teams (0.969 vs. 0.665) or, on average, 0.304 hours (18 minutes a day) higher. All differences in average EFFICIENCY, REJECTION RATE, and DOWNTIME before and after team membership are statistically significant at the 1 percent level.

For team members, we undertake similar analyses depending on whether or not team membership resulted from management solicitation and whether team members have education

is apt to be high (Glaeser *et al.*, 1999). Consequently we might expect that the potential for the introduction of teams fostering trust is especially high in such circumstances.

²³ During the 35-month period, no team member quit participating in his/her team to become a non-team member.

beyond high school or not.²⁴ These findings are reported in table 2. For all sub-groups of team members we find similar directional changes in all three measures after team membership. All differences in average EFFICIENCY, REJECTION RATE, and DOWNTIME before and after team membership are statistically significant at the 1 percent level except for EFFICIENCY of team members without education beyond high school. Solicited team members show a substantially greater improvement in the REJECTION RATE than unsolicited team members, whereas the size of EFFICIENCY gains seem to be somewhat smaller for solicited members than for unsolicited members. Perhaps most interestingly, unsolicited members increase their DOWNTIME after team membership considerably more than solicited members, suggesting possible opportunistic behavior by unsolicited members. With regard to education, the size of improvements in EFFICIENCY and REJECTION RATE appear to be greater for more educated workers than for less educated workers, whereas the size of DOWNTIME increase seems to be comparable, suggesting a possible complementarity between education and teams.

Finally, to see if team members are better performers to begin with than non-members, we add descriptive statistics for non-team members to Table 2. In fact the data show that it is non-members that have higher EFFICIENCY and lower REJECTION RATE (compared to team members, at least before they joined teams). In other words, there appears to be no “cherry picking.” In addition, team members (at least before they joined teams) had lower DOWNTIME than non-members. Thus, there appears to be no evidence that team members are prone to have more downtime to begin with than non-members.

²⁴ The data on whether or not each team member was solicited by management are provided by the full-time consultant who has been in charge of all team activities since the introduction of offline teams.

V. Empirical Strategy and Findings on Worker Performance

To investigate with more precision the suggestive findings from the previous section, we undertake a number of exercises. Our baseline model, which we use to investigate our core hypotheses concerning the impact of teams on productivity and quality, is a simple fixed effects model:

$$(1) \quad P_{it} = \alpha \text{MEMBER}_{it} + \beta (\text{DAYS IN TEAM})_{it} + (\text{individual specific fixed effects}) \\ + (\text{monthly time dummy variables}) + u_{it}$$

where P_{it} is performance of worker i in day t ; MEMBER_{it} is a dummy variable which takes the value of 1 if worker i is a team member in day t , and the value of zero otherwise. As previously indicated the available data enable us to consider three measures of P_{it} : (i) EFFICIENCY; (ii) REJECTION RATE; and (iii) DOWNTIME. The estimated coefficients on MEMBER_{it} are used to test whether or not team membership affects individual performance. In addition, we include $(\text{DAYS IN TEAM})_{it}$ (the number of days in a team in 100 days) in order to test hypotheses concerning whether or not the impact of organizational changes introduced alone can deliver sustained benefits in firm performance. That is, in the absence of complementary initiatives the performance effects of team may be expected to change (deteriorate) as that program continues without the benefit of other reforms.

We include individual specific fixed effects to capture the time-invariant unobserved heterogeneity of our workers. In particular, individual specific fixed effects will attempt to control for differences among workers in their innate abilities. If workers with high innate abilities are more likely to join teams, the coefficients on MEMBER might indicate the effects of superior innate abilities of workers in general as well as the actual effects of team membership. Individual specific fixed effects will help separate the two effects.

We also include 34 monthly time dummy variables to capture time-specific shocks to PARTS that are common to all production workers. (There are actually 35 monthly time dummy

variables from January 1999 through November 2001. We use the January 1999 time dummy variable as a reference month.)

To see if the estimated coefficients on $MEMBER_{it}$ and $(DAYS\ IN\ TEAM)_{it}$ change when the tenure of the worker is controlled for, we also considered an additional specification. In this estimate, the tenure of the worker (the number of days for which he/she has been with PARTS) and its square are added to Eq. (1).²⁵

The coefficient on $MEMBER_{it}$ can be interpreted as gauging how much each individual worker's performance changes as a result of his/her participation in an offline team. The coefficient on $(DAYS\ IN\ TEAM)_{it}$ can be interpreted as indicating to what extent the initial impact of team participation changes as his/her team experience increases.

Note that the coefficient on $MEMBER_{it}$ is not capturing the *indirect* spillover effect of team participation on performance of non-team members and hence the overall factory-wide performance. Estimation of such overall team effects is usually subject to a selection issue. That is, all workers realize that the introduction of offline teams signifies that the firm's HR strategy is shifting more towards a high performance/high involvement HR system whereby high-ability workers are more highly valued and low-ability workers find work more challenging, demanding and difficult. As a result, low-ability workers find the shift an unwelcoming event and are more prone to quit than high-ability workers. If this is the case, the overall performance of the firm will improve even if there is no motivational effect of the introduction of teams on team members since the introduction of teams weeds out low-ability workers.

However, we are not studying such overall team effects; rather we are studying changes in performance of the same worker before and after joining a team. At the same time, we

²⁵ To avoid multicollinearity between time dummy variables and TENURE, we also tried to restrict the sum of all monthly time effects to be zero. The estimated coefficients on MEMBER and DAYS IN TEAM prove to be insensitive to such a restriction.

recognize that if poorly performing team members are more likely to quit than are other team members, then the estimated coefficients on $MEMBER_{it}$ would be subject to a similar selection issue (or we would be overestimating the motivational effect on team members of team participation). However, our data reveal that no team member quit during the 35-month study period. This total absence of attrition from teams was confirmed by managers of PARTS. Hence, we expect the selection issue to be much less relevant in this study. To confirm this conjecture, we will examine whether the estimated coefficient on $MEMBER_{it}$ will change significantly when including those operators who left PARTS during the 35-month period.

Table 3 summarizes the fixed effect estimates of Eq. (1). We begin first by discussing findings on the impact of team membership on EFFICIENCY (we drop subscripts for exposition from now on.) A clear and consistent finding is that there is a positive and significant effect on EFFICIENCY of MEMBER thus indicating that team membership leads to improvements in productivity. This effect is apparent in both specifications (with and without controlling for the possible tenure effect) and is estimated at plausible levels (about a 3% gain in EFFICIENCY).

Furthermore, the negative coefficient on DAYS IN TEAM indicates that the positive team effect will diminish as time goes by. Specifically, the positive team effect on EFFICIENCY will fall by about 10% per 100 days in team. As such this provides evidence that is consistent with the hypothesis that, in the absence of complementary initiatives, the beneficial effects of measures introduced alone (such as teams) can be expected to be short-lived as the motivational effects of employee involvement alone are undermined over time. Note that our evidence is also consistent with the Hawthorne effect. However, later we will provide evidence that the Hawthorne effect interpretation may not be particularly relevant to our case.

The effects of team membership on the REJECTION RATE are also reported in the same table. Essentially the results reported parallel those for the previous measure of performance, i.e. EFFICIENCY. The key result is a clear and consistent finding of a negative and significant effect

on the REJECTION RATE of MEMBER, thus indicating that team membership results in an improvement in quality. While the average improvement in the REJECTION RATE is a modest 0.15 percentage point, this represents a 27% improvement in the average REJECTION RATE. Furthermore, we observe that the team effect will weaken as DAYS IN TEAM rises, specifically diminishing by about 16% in 100 days after the average worker becomes a team member. As such this provides further support for theorists who argue for the need for complementary initiatives.

Finally we examine the impact of teams on DOWNTIME. Again the evidence is quite persuasive. In both specifications (with and without controlling for tenure effects), membership in a team is accompanied by a positive and significant effect on DOWNTIME -- team membership results in more downtime. Specifically, for the average team member there is a 0.25 hour (15 minutes) increase in daily DOWNTIME to begin with. This is consistent with hypotheses that predict the existence of significant initial costs to investing in participatory institutions such as teams. The major cost in this case is the forgone operation hours of team members since team meetings are held during regular working hours. In addition, the estimated coefficients on DAYS IN TEAM are negative and statistically significant, falling by about 6% in 100 days after becoming a team member. This indicates that the cost of teams will diminish as team members increase their experience with teams and learn how to run their team meetings effectively.

As we discussed earlier, to check whether our estimates are sensitive to the inclusion of those workers who left PARTS during the period, we re-run the regressions reported in Table 3A but also include data for operators who left during the period. These results are reported in Table 3B. As expected, it is clear that our key findings are unaffected by the inclusion of these data for

“job leavers”. The size and direction of all coefficients are essentially unaltered by the use of this larger data set.²⁶

Before turning to additional hypotheses concerning management solicitation and education, we briefly consider indirect spillover effects. In Figure 1 we plot the estimated effects of Efficiency from Eq. (1) over time along with the number of offline team members. Similarly, Figure 2 shows the estimated effects of Rejection Rate from Eq. (2) over time along with the number of offline teams. Both Figures show productivity and quality improving over time, though quality improvements appear more promptly. These patterns coincide with the diffusion of offline teams among operators at PARTS and suggest the presence of indirect spillover effects as captured by estimated time effects. However, since the estimated time effects also include the effects of other external shocks common to all operators at PARTS, such as demand shocks and trends, unfortunately the precise magnitude of the indirect spillover effects cannot be identified.²⁷

To study team effects separately for solicited and unsolicited team members, we modify Eq. (1) as follows:

$$\begin{aligned}
 (2) \quad P_{it} = & \alpha_S(\text{SOLICITED MEMBER})_{it} \\
 & + \beta_S(\text{SOLICITED MEMBER})_{it} * (\text{DAYS IN TEAM})_{it} \\
 & + \alpha_U(\text{UNSOLICITED MEMBER})_{it} \\
 & + \beta_U(\text{UNSOLICITED MEMBER})_{it} * (\text{DAYS IN TEAM})_{it} \\
 & + (\text{individual specific fixed effects}) + (\text{monthly time dummy variables}) + u_{it}
 \end{aligned}$$

where $(\text{SOLICITED MEMBER})_{it}$ is a dummy variable which takes the value of 1 if worker i is a solicited team member in day t , and the value of zero otherwise; and $(\text{UNSOLICITED MEMBER})_{it}$ is a dummy variable which takes the value of 1 if worker i is an unsolicited team member in day t , and the value of zero otherwise.

²⁶ Since no personnel records are available for those who left during the sample period, we are unable to consider the tenure of the worker as an additional control.

²⁷ Interviews with the CEO, the production manager, and the manager in charge of teams all confirm that there were no major technological changes (such as the introduction of new machines) at PARTS during the study period.

MEMBER)_{it} is a dummy variable which takes the value of 1 if worker i is an unsolicited team member in day t, and the value of zero otherwise.

Likewise, to study the team effects separately for team members with and without education beyond high school, we modify Eq. (1) as follows:

$$\begin{aligned}
 (3) \quad P_{it} = & \alpha_M(\text{MORE EDUCATED MEMBER})_{it} \\
 & + \beta_M(\text{MORE EDUCATED MEMBER})_{it} * (\text{DAYS IN TEAM})_{it} \\
 & + \alpha_L(\text{LESS EDUCATED MEMBER})_{it} \\
 & + \beta_L(\text{LESS EDUCATED MEMBER})_{it} * (\text{DAYS IN TEAM})_{it} \\
 & + (\text{individual specific fixed effects}) + (\text{monthly time dummy variables}) + u_{it}
 \end{aligned}$$

where (MORE EDUCATED MEMBER)_{it} is a dummy variable which takes the value of 1 if worker i has education beyond high school and is a team member in day t, and the value of zero otherwise; and (LESS EDUCATED MEMBER)_{it} is a dummy variable which takes the value of 1 if worker i does not have education beyond high school and is a team member in day t, and the value of zero otherwise.

Tables 4A reports the fixed effect estimates of Eq. (2). The most striking and statistically significant difference in the team effects between solicited and unsolicited team members lies in the time profile of the team effects. The performance gains from team membership will fall as unsolicited members spend more time in teams whereas they will not fall as solicited members spend more time in teams (in fact, the positive EFFICIENCY gains from team membership will rise significantly as time passes for solicited members). Furthermore, concerning DOWNTIME, again as expected, the increase in DOWNTIME as a result of team membership is considerably greater for unsolicited members than for solicited members. In addition, such increase in DOWNTIME will fall more slowly for unsolicited members as time goes by. All these differences between solicited and unsolicited members are found to be statistically significant at least at the 5 percent level. Finally, the team effects on EFFICIENCY and the REJECTION

RATE are found to be greater for solicited team members than for unsolicited members although we are unable to reject the null hypothesis of $\alpha_S = \alpha_U$ at the 10 percent level.

In sum, the evidence is consistent with our conjecture that skilful personnel managers will have a better sense of those individuals who will likely be better fits as team members and also which individuals are more likely to continue to get motivated and to learn useful skills in teams. Our findings also support the hypotheses that some of those employees who volunteer to become team members with no management encouragement may be behaving opportunistically — they are simply seeking a paid break from their daily production work. Furthermore our findings support the signaling hypothesis that management solicitation serves as a credible signal to solicited workers that management considers them in the viable pool of candidates to become line supervisors. Finally, we find no evidence that the performance-enhancing effect of team membership erodes over time for solicited members whereas we do find such evidence for non-solicited members. As such, these findings are not consistent with the Hawthorne effect which predicts that the dissipation of the performance-enhancing effect of teams over time will be particularly relevant to solicited members.

To further shed light on the observed differences in the team effects between solicited and unsolicited team members, we run a “pre-program” regression. That is,

$$(4) \quad P_{it} = \alpha + \beta_S(\text{SOLICITED MEMBER})_i + \beta_U(\text{UNSOLICITED MEMBER})_i \\ + \gamma X_{it} + (\text{monthly time dummy variables}) + u_{it}$$

where t is from January 1, 1999 to May 31, 1999 (i.e. the period prior to the introduction of offline teams); $\text{SOLICITED MEMBER}_i = 1$ if worker i eventually becomes a solicited member, 0 otherwise; $\text{UNSOLICITED MEMBER}_i = 1$ if worker i eventually becomes an unsolicited member, 0 otherwise; and X_{it} is a vector of personal characteristics of worker i in day t that may affect his/her performance and our data enable us to control for his/her education level, gender,

tenure, and its square. For example, when measuring P_{it} by efficiency, the estimated coefficients on (SOLICITED MEMBER)_i and (UNSOLICITED MEMBER)_i indicate whether solicited members (unsolicited members) were initially (prior to the introduction of teams) more or less productive than those who never become team members, after controlling for personal characteristics and time effects. If statistically significant differences in the estimated coefficients between solicited and unsolicited members emerge, potentially this will provide additional insights into the process by which managers solicit team-members.

Table 4B summarizes the OLS estimates of Eq. (4). After controlling for tenure, education, gender and time effects, prior to the introduction of teams, solicited team members were found to be 9 percentage-points less efficient than non-team members, while unsolicited team members were 13 percentage-points less efficient than non-team members. The efficiency differential between solicited and unsolicited team members is found to be statistically significant at the 10 percent level. The quality measure (rejection rate) results suggest that solicited team members were initially producing substantially more defects than non-team members, whereas unsolicited team members were similar to non-team members in terms of their rejection rates. The quality differential between solicited and unsolicited team members is statistically significant at the 1 percent level. Finally, for solicited members, downtime was initially more than 20 minutes less per day than for non-team members, whereas downtime for unsolicited members was initially 15 minutes less than for non-team members. The pre-program differential in downtime between solicited and unsolicited members is found to be statistically significant at the 10 percent level.

In short, our pre-program regression results suggest that even after controlling for observable individual characteristics of workers and time effects, management solicitation appears to have been focused on underperforming operators, in particular those with more room for quality improvement. In addition, the targeted operators were also initially spending more

time on production and hence had more room for downtime to increase, such as through team meetings.

Conceivably, initially solicited operators might have been operating particularly difficult machines which resulted in low efficiency and high rejection rates and, after participating in teams, they might have been assigned to easier machines. If this were in fact the case, then the observed efficiency and quality gains from team membership would simply have resulted from such systematic machine reassignments. However, based on extensive and separate interviews with the CEO, the general production manager and a key contact who is in charge of teams, we are persuaded that the introduction of team membership was not accompanied by any systematic task reassignments.²⁸

The fixed effect estimates of Eq. (3) are reported in Table 5. The most significant difference between more and less educated team members is found in the team effects on the REJECTION RATE. The estimated coefficient on MEMBER is statistically significant only for more educated team members, implying that the quality gains from team membership are felt only for team members with more education. The estimated coefficient on (LESS EDUCATED MEMBER)*(DAYS IN TEAM) is, however, negative and statistically significant. This suggests that, for less educated team members, while there is no immediate team effect on the REJECTION RATE, with the passage of time they begin to learn to convert their team experiences into their daily performance in quality assurance. For DOWNTIME, as educated team members engage in learning by doing, the cost of team membership (increased downtime) will diminish. No such significant learning effects are found for less educated workers. For EFFICIENCY, as expected, the team effects appear to be greater and more long-lasting for more educated team members than for less educated team members, although these differences are

²⁸ In addition, it is difficult to reconcile the machine reassignment interpretation of the team effects with the dissipation of the effects over time.

found to be statistically insignificant at the 10 percent level. Overall, our findings are generally consistent with the hypotheses that there is a complementarity between education and teams.

VI. Conclusions and Implications

We use extraordinary data to provide some of the most reliable evidence to date on diverse hypotheses concerning the economic impact of offline teams, which are an increasingly important and common form of employee participation. Our core hypotheses relate to the *direct* impact of offline teams and employee involvement on individual (and thus) business performance. Based on daily data for various measures of performance including rejection (quality) and production rates for all operators in a single plant during a 35 month period, we find that membership in offline teams results in enhanced enterprise performance. While the size of these initial effects depends on the particular specification, gains in efficiency average about 3%, which is a quite believable number given the relatively limited scope that the production process provides for discretionary effort to affect output rates. In our reading of the literature, we find no econometric estimates on the productivity effect of *offline* teams to which our estimates can be compared. However, Hamilton, Nickerson and Owan (2002) report a 14-percent gain in productivity from the adoption of *online* teams which is considerably larger than our estimated productivity gain. We believe that one of the main reasons for the relatively small productivity gain estimates in our study is that we are capturing only the *direct* impact on motivation, goal alignment and human capital formation (and thus productivity) for team members of the adoption of offline teams. Our estimated productivity gain does not include possible *indirect* spillover effects, such as teams solving various productivity problems (and thus enhancing the overall efficiency of the workplace), and team members engaging in peer monitoring and knowledge sharing with non-team members (and hence enhancing non-members' productivity). Consequently our findings may be viewed as lower bound estimates of the effects

of teams. The gross gains from teams (and which include indirect spillover effects) may well be greater than what we have captured by our estimates of the direct gains.

We also provide what may be the first rigorous estimates of the impact of any form of employee involvement, including teams, on product quality. According to our estimates, we find that team membership leads to rejection rates improving by about 27%. These findings on output and quality are consistent with hypotheses that predict that the introduction of (and membership in) teams will produce more trust by employees in management, improved goal alignment between managers and employees and thus enhanced discretionary effort and improved attention to quality. While our evidence may be viewed as complementary to other studies, we again underscore the most unusual nature of our data. Thus, following the adoption of a high performance work system that includes teams among other innovative work practices, Ichniowski, Shaw and Prennushi (1997) also find a statistically significant positive impact on a physical measure of product quality of steel finishing lines. But whereas we use individual worker data, Ichniowski, Shaw and Prennushi (1997) use plant-level data. Also Batt (1999) finds a statistically significant positive effect of online teams for call center workers, though a self-reported rather than an objective measure of quality is used.

We also find clear evidence that the improvements in enterprise outcomes are not sustained at their initial levels.²⁹ Improvements tend to dissipate over time at a rate of 10 to 16% per 100 days in team. However this finding is unsurprising to those who stress the need for complementarities in HR initiatives. It is, for example, consistent with theorists who predict that for sustained improvement in business performance enhanced employee involvement must be accompanied by financial participation.

²⁹ As such, our evidence is consistent with the QC circle literature that generally reports the transitory nature of the benefits of QC circles (e.g., Lawler III, 1986, Griffin, 1988, Levine, 1995).

The introduction of teams is also initially accompanied by significant costs as rates of downtime increase. However, consistent with those who predict team-learning effects, these costs diminish over time. As such, HPWPs are best viewed as investments.

Moreover, we find differences in performance following team membership for members solicited by managers compared to those who volunteer as well as differences in pre-program performance. These findings are consistent with various hypotheses including management's ability to observe the relevant worker qualities, tournament incentive and opportunistic behavior by employees, but inconsistent with hypotheses based on Hawthorne effects. Finally, we find evidence of a complementarity between teams and formal education.

One implication of our finding concerns the payoffs to possible managerial choices that are available to firms today. Some economic theorists argue that firms that operate in today's competitive labor and product markets, have very little discretion in setting wage, employment and human resource management practices. Consequently, these practices are predicted to be broadly similar across firms in similar situations. However, the evidence presented in this paper provides evidence that firms can introduce changes (such as teams) and that, as in the case of PARTS, when a serious attempt is made to introduce an innovative HR policy such as teams, non-negligible benefits to firms are often delivered. Our empirical findings provide much more solid support than was perhaps previously available for those who hypothesize that participatory practices can enhance business performance, even in settings where employee tasks are fairly simple and employees are relatively low-skilled and the firm uses relatively simple technologies to produce components and employs rural low-wage workers with limited education. Finally, our findings indicate that the payoffs to such single innovations may not persist and that the design of HR policies in firms needs constant attention. To provide for enduring gains in firm performance, most likely will require the introduction of complementary initiatives.
