The Role of Caseworkers in Unemployment Insurance: Evidence from Unexpected Absences

Amelie Schiprowski * **April** 2017

Abstract

Caseworkers are the primary human resource used to match unemployed workers to jobs. This paper analyzes how the quantity and quality of interactions with caseworkers affect the exit from unemployment. I exploit exogenous variation in unexpected absences among Swiss UI caseworkers. Using large-scale administrative data, I find that job seekers who lose an early meeting with their caseworker stay on average 10 days longer in unemployment. This effect strongly increases with caseworker productivity at work and with tenure. Finally, absences induce negative spillover effects on the performance of present colleagues, who have to cover additional workload. Beyond the context of unemployment, the results point towards high costs of absenteeism in contexts in which workers interact with clients.

1 Introduction

Most welfare states rely on the human resources of caseworkers to reintegrate unemployed workers into the labor market. Caseworkers operate as the direct intermediary between job seekers and the unemployment insurance (UI) system.¹ Through regular meetings, they provide information, motivate effort and generate pressure for active job search.² In this paper, I assess how the number and quality of early interactions with caseworkers affects the duration of unemployment spells. I exploit unexpected work absences, which provide the rare opportunity to study quasi-random variation in how much individuals interact with their caseworker.

If policy makers want to invest into the human resources of caseworkers, they have mainly two margins at their disposal: on the one hand, they can augment the quantity of job seeker-caseworker interactions, for instance by reducing caseloads and increasing the time spent on each job seeker. On the other hand, they can target quality, by improving the productivity of existing caseworkers or the selection of individuals into the profession. Caseworker absences provide quasi-experimental variation along both margins: first, job seekers experience a lowered quantity of interactions, as their absent caseworker cannot be fully replaced.³ Second, they interact with a different caseworker when a replacement occurs. As a consequence, they can experience a change in caseworker quality.⁴ I first estimate the average effect of caseworker absences, including an analysis of spillover effects on present colleagues. In a second part, I exploit heterogeneity in the absent caseworker's productivity to disentangle the relative importance of quantity versus quality effects.

The study is based on administrative data from the Swiss UI, covering the full population of job seeker-caseworker matches registered between 2010 and 2012. The data provide high frequency information on all planned and realized meetings between job seekers and caseworkers. Unexpected absences can therefore be measured through the incidence of meeting cancellations: when a caseworker cancels all scheduled meetings, she most likely planned to come to work, but was retained by an unexpected incidence.

For identification, I exploit that the exact caseworker-specific timing of an absence is as good

¹Caseworkers are also commonly used in other types of welfare systems, such as disability insurance.

²The OECD 2015 Employment Outlook (OECD, 2015) describes the different tasks of caseworkers employed by public employment services in OECD countries.

³To the best of my knowledge, the only evidence on the effects of caseworker interactions stems from a non-experimental study by Van den Berg et al. (2012), who apply a timing-of-events approach and find that the outflow from unemployment increases after job seekers meet their caseworker. Indirect evidence comes from Hainmueller et al. (2016), who use aggregate data at the level of local employment offices and show that the outflow from unemployment increases in response to a policy-induced caseload reduction.

⁴Previous non-experimental evidence shows that specific dimensions of heterogeneity between caseworkers can affect job search outcomes. Behncke et al. (2010a) apply propensity score matching to show that tough caseworkers perform better. Based on duration analysis, Arni et al. (2015) find that the caseworker's intended use of carrots and sticks affects the exit from unemployment. Behncke et al. (2010b) focus on the quality of the match between caseworkers and job seekers. Using propensity score matching, they show that caseworkers are more successful when sharing common traits with a given job seeker.

as random from the job seeker's perspective. To this end, I condition on caseworker and calendar month fixed effects, excluding time-constant productivity differences between caseworkers and aggregate time shocks from the identifying variation.⁵ Conditional on these fixed effects, neither job seeker characteristics nor workload predict the incidence of caseworker absences. Placebo tests further corroborate the approach by demonstrating that future absences do not affect current outcomes.

Results show that job seekers remain unemployed longer when their caseworker is absent at least ten workdays during months 1-3 or 4-6 of unemployment.⁶ The probability to exit within six months decreases, on average, by 2.8 percentage points (5% relative to the mean), and the unemployment duration increases by 10 days. To interpret these effects, I show that absences of at least ten workdays lead to an average loss of one meeting with the assigned caseworker over the first six months of unemployment (40% relative to the mean). About half of this loss is replaced by meetings with other caseworkers in the office. In this respect, the estimates are a lower bound to the effect of absences in contexts without replacement mechanisms.

In an additional analysis, I test for spillover effects of absences within public employment service (PES) offices. To this end, I analyze how variation in the office-specific caseworker absence rate affects job seekers with present caseworkers, conditional on caseworker and month fixed effects.⁷ I find that job seekers have less meetings when the office-specific absence rate increases. They further stay unemployed longer, confirming the economic relevance of caseworker workload.

To inform policy design, it is crucial to understand the importance of quantity versus quality effects of caseworker-job seeker interactions, as they imply different investments in terms of human resources. Therefore, the second part of the analysis decomposes average effects according to the absent caseworker's productivity at work. Provided that replacements are in expectation performed by the average caseworker in the office, absences of caseworkers of average productivity should not cause any quality effect.⁸ If the absent caseworker is, however, more productive than the average, the meeting with a replacement of average productivity is expected to induce a loss. The reverse applies when the absent caseworker is less productive than the average.

I estimate a caseworker's additive productivity at work as her fixed effect on the six-months exit probability of job seekers who are unaffected by an absence.⁹ The approach is closely related to

⁵The use of worker-time specific variation in workplace presence is closely related to work by Mas and Moretti (2009) and Herrmann and Rockoff (2012), who study peer effects in the workplace and the effects of teacher absences on student test scores, respectively.

 $^{^{6}}$ If the job seeker is exposed to less than 10 days of absence over a three-months period, there is no effect on the exit from unemployment.

⁷For each individual *i*, I measure the share of individuals with absent caseworkers entering unemployment in the same office and calendar quarter as *i*. This share is computed as a leave-out mean, excluding individuals assigned to the same caseworker as *i*.

⁸I do not exploit heterogeneity in the replacement's productivity, as it is potentially endogenous whether and by whom a meeting is replaced.

⁹This measure is clearly limited to medium run job finding as one dimension of caseworker productivity.

the estimation of teacher value added, discussed, e.g., by Chetty et al. (2014a,b). By comparing caseworkers within offices, I hold the working environment constant.¹⁰ The assignment of job seekers to caseworkers is based on availability or on observable job seeker characteristics included in the regression, ensuring that caseworker fixed effects can indeed be interpreted as a measure of productivity.

Results confirm that the average effect of an absence masks substantial heterogeneity. If the absent caseworker ranks in the medium productivity tercile, the probability to exit within six months decreases by 2.6 percentage (5% relative to the group-specific mean). Strikingly, absences of caseworkers in the lowest tercile induce a zero net effect: for them, the loss in meeting quantity is apparently offset by a gain in productivity due to the replacement by a better caseworker. In turn, job seekers with a caseworker in the highest productivity tercile suffer from the replacement by a worse caseworker. Their exit probability within six months decreases by 6.4 percentage points in response to the absence (9% relative to the group-specific mean). This strong effect is mostly driven by exits to stable jobs, suggesting that productive caseworkers achieve good job matches. To ensure that these heterogeneities can be interpreted as pure quality effects, I show that absences of caseworkers in the three terciles equally reduce the meeting quantity.

I further explore whether the usage of active labor market programs explains the observed effects of caseworker absences and their heterogeneity. Results show that the assignment of training programs and vacancies, as well as the intensity of job search monitoring decrease, on average, in response to caseworker absences. However, the effects hardly vary by caseworker productivity. This suggests that the success of caseworkers is mostly determined by unobserved personal qualities and counseling techniques, rendering the replacement of productive caseworkers difficult. The intuition that caseworkers have a large individual impact is in line with previous findings from other economic contexts. A large literature documents that teacher quality is a central determinant of test scores and labor market outcomes of students (e.g., Chetty et al., 2014a,b; Rivkin et al., 2005; Rockoff, 2004; Rothstein, 2010). Further, Lazear et al. (2015) find large effects of supervisors on worker productivity in firms. Jäger (2016) shows that firms face difficulties in finding replacements after exogenous worker separations, in particular when human capital is largely firm-specific. In a final analysis, I show that the negative effect of absences also increases with tenure and

 $^{^{10}}$ The regressions used to measure caseworker effects are run on the level of the canton. They contain interacted office \times quarter fixed effects as well as job seeker covariates. They are performed only on job seekers whose caseworker does not have an absence of ten or more days during months 1-3 or 4-6 after entry. This avoids that job seekers who are treated by an absence contribute to the estimated productivity at work (c.f. the intuition of a leave-out mean).

¹¹In addition, it is possible that productive caseworkers target programs to the right individuals. Previous findings show that, on average, caseworkers do not perform well in targeting active labor market programs. Schmieder and Trenkle (2016) use an RDD design to show that caseworkers do not take individual search incentives induced by the duration of benefits into account when assigning treatments. They conclude that caseworkers apply programs in a bureaucratic way. Lechner and Smith (2007) use propensity score matching and find that the payoffs of treatment assignments made by a statistical program exceed those made by caseworkers.

experience, suggesting that caseworkers accumulate task-specific human capital which makes them less replaceable.

The strong role of UI caseworkers identified in this paper provides a novel perspective on the large literature studying the effectiveness of labor market programs. As pointed out in the surveys by Card et al. (2010, 2015), these studies tend to find close to zero average effects in the short run and slight positive effects in the longer run. My results suggest that the potential to foster early unemployment exits lies rather in high quality counseling by caseworkers than in an increased usage of active labor market programs. Most related to this result, Huber et al. (2017) present a semi-parametric mediation analysis showing that the success of tough caseworkers is not driven by particular program assignments.¹²

In addition, this paper adds to the scarce evidence on the micro-foundations of the job matching function and on the role of public institutions. One part of the literature investigates how (unemployed) workers direct their search to a job match (e.g. Blau and Robins, 1990; Holzer et al., 1991; Marinescu and Wolthoff, 2016). A few studies have pointed out that the efficiency of the public employment service (PES) is a central driver of unemployment exits. Using structural estimation techniques, Fougère et al. (2009) and Launov and Wälde (2016) show that a more productive PES increases outflows from unemployment.¹³ My results add an additional layer to these findings, by showing that public human resources substantially influence the job matching process.

Finally, my results reveal substantial economic costs of workplace absenteeism. In the U.S., 1.5% of working time was lost in 2016 due to absences (U.S. Bureau of Labor Statistics, 2017). The causal evidence on the costs induced by absences is, however, limited to Herrmann and Rockoff (2012), who find that teacher absences negatively affect student test scores. The results of my paper confirm the notion that worker absences may induce large costs. They further identify negative spillover effects on present workers and point towards low replaceability of highly productive workers.

The remainder of the paper is structured as follows: section 2 lays out the institutional context and the data sources. It further shows how absences are measured and assigned to the job seeker's unemployment spell. In section 3, I discuss the conceptual link between caseworker absences and the exit from unemployment. Section 4 presents the empirical analysis on the average effects of caseworker absences. Section 5 decomposes the effect according to the absent caseworker's productivity, and section 6 concludes.

 $^{^{12}}$ The paper by Huber et al. (2017) relates to a previous study by Behncke et al. (2010a), who use propensity score matching to show that tough caseworkers are more successful.

¹³Pissarides (1979) and Jung and Kuhn (2014) reach similar conclusions based on theoretical search-and-matching models.

2 Institutions and Data

2.1 Caseworkers in the Swiss UI

In Switzerland, job seekers are entitled to UI benefits if they have contributed for at least six months during the two previous years.¹⁴ The potential duration of unemployment benefits is usually 1.5 years for eligible prime age individuals, but varies by the job seeker's contribution period, age and family situation. The replacement ratio ranges between 70% and 80% of previous earnings, depending on the individual family situation and the level of past earnings. As in most OECD countries, job seekers are monitored in their job search activities and given active counseling through the intermediary of caseworkers.

Job seekers have on average about two caseworker meetings during the first three months of unemployment. The average meeting lasts 35 minutes. During the meetings, caseworkers provide information, support and monitor the job search process, assign training programs and refer vacancies. Job seekers risk benefit sanctions for missing a caseworker meeting. Caseworkers are organized within the unit of Public Employment Service (PES) offices. When individuals register at the PES to claim benefits, they are mostly assigned to a caseworker based on availability. Further criteria may e.g. be the job seeker's education level, previous occupation or place of residence. The assignment mechanism is fixed by the local UI authority and cannot be influenced by the job seeker. As the default, meetings take place with the assigned caseworker. If the assigned caseworker is unexpectedly absent on the day of a scheduled meeting, the meeting can be canceled, re-scheduled, or replaced by a different caseworker.

2.2 Data and Measurement of Caseworker Absences

Data Sources The empirical analysis is based on individual level data from the Swiss UI register, covering the universe of job seekers who entered formal unemployment between 2010 and 2012. ¹⁵ The database includes extensive information on the entry into and exit from formal unemployment, socio-demographics, potential benefit duration as well as employment and unemployment histories. It reports the job seeker's public employment service (PES) office and the assigned caseworker, as well as the type and time of different treatment assignments (e.g., training programs or benefit sanctions). Most importantly for the purpose of this paper, the data include all scheduled meetings on the job seeker-caseworker level, with the exact date and time of each meeting. It is further reported whether a scheduled meeting was realized, canceled, re-scheduled or whether the job

¹⁴To be eligible for the full benefit period, the contribution period extends to 12 to 22 months, depending on the individual situation.

¹⁵Data on earlier entry cohorts are available, but do not systematically report unrealized caseworker meetings. As these are essential to measure caseworker absences, I do not cannot include earlier cohorts in the analysis.

seeker did not appear at the meeting.

I restrict the analysis to full-time unemployed job seekers aged 20-55, who are eligible for UI and not eligible for disability benefits. I drop 1.11% (N=4,351) of observations because the caseworker assigned to the job seeker never appears in the meeting database, and additional 2.15% (N=8,520) because the caseworker has less than 30 cases. These have a high likelihood of being mis-classified assignments.

The sample used in the empirical analysis contains 382,123 job seekers assigned to 2,269 caseworkers. Caseworker assignments can be updated during the unemployment spell. As these updates may occur in response to caseworker absences, they are potentially endogenous. I thus retain the assignment made up to one week after the job seeker's entry into unemployment: if the job seeker's caseworker assignment gets updated during the first week of unemployment, I use the updated assignment. This allows correcting for erroneously made initial assignments. Figure 1 reports how likely a job seeker is to meet her assigned caseworker during months 1-12 of the unemployment spell. About 75% of job seekers meet their assigned caseworker in the first month of unemployment. This fraction drops strongly over the unemployment spell to about 50% in month three, 40% in month six and about 30% in month twelve. This drop is, on the one hand, due to the fact that the meeting frequency decreases over the spell. On the other hand, the likelihood of a change in the caseworker assignment increases over the spell. From anecdotal evidence, it is common practice that caseworkers switch cases after six months. As only initial caseworker assignments can be considered exogenous to the dynamics of the unemployment spell, I focus on the role of caseworkers during the first six months of unemployment.

[Insert Figure 1]

Measurement of Caseworker Absences I exploit the meeting database to identify when the caseworker planned to come to work, but was retained by an unexpected incidence. In the data, such absences should translate into a sequence of scheduled, but unrealized meetings.¹⁸

Therefore, I define an unexpected absence as starting during the day at which none of a caseworker's scheduled meetings is realized. Unrealized meetings take the status "scheduled", "canceled" or "re-scheduled". The two other possible categories are "realized" or "job seeker did not appear". As meeting cancellations can also be made by the job seeker, ¹⁹ I apply a conservative approach to ensure that unrealized meetings reflect caseworker absences: I require that during

¹⁶Results are robust to modifying this cutoff (c.f. section 4).

¹⁷Results are robust to not updating assignments or to using updates made up to week 2 instead (c.f. section 4).

¹⁸The data do not provide the reasons of a caseworker's absence.

¹⁹In practice, job seekers are obliged by the UI law to participate at caseworker meetings and can therefore not cancel easily.

two or more of a caseworker's subsequent day entries, at least two meetings were scheduled and not realized.²⁰ It is highly unlikely that such a sequence of consecutively unrealized meetings by one caseworker is caused by job seeker cancellations. The absence duration is computed as the number of workdays between the first day of the absence and the first day at which the caseworker is reported to conduct a meeting again.²¹

Figure 2 plots a time series of the monthly share of caseworkers who start an unexpected absence. The share fluctuates around 3.5% and peaks during the winter months, most likely reflecting an increased incidence of sickness days. Table 1 shows caseworker-level summary statistics on the number of workdays and the number of absent days. The average caseworker unexpectedly misses 2.3% of her workdays. Taken over a year with 230 workdays, 22 this means that, on average, 5.3 workdays are missed due to an unexpected absence. This number appears of reasonable size, as the the average Swiss public sector employee missed 63 hours (≈ 7.5 days) per year in 2015 (Swiss Federal Statistical Office, 2016), which also contain anticipated absences (e.g., planned surgeries). 23

[Insert Figure 2 and Table 1]

To assign absences to the individual unemployment spell, I count the number of workdays during which the job seeker's caseworker is absent in a given three-months period t after entry. Figure 3 illustrates the assignment of caseworker absences to job seekers over the course of the unemployment spell. For instance, the variable $ABS_{j(i),1-3}$ contains the number of days during which caseworker j was absent during months 1-3 after job seeker i's entry (excluding week 1, during which caseworker assignments are allowed to be updated). $ABS_{j(i),t}$ is an intended treatment, as it does not condition on the job seeker's survival in unemployment at the time of the absence. The empirical analysis will scale the effects of the intended treatment to the average treatment effect on job seekers who are still unemployed at the first day of caseworker absence.

The analysis focuses on absences occurring up to month six. Later absences will be used to run placebo tests. Table 2 reports summary statistics on how job seekers are affected by caseworker absences. The average job seeker's caseworker has 0.45 workdays of unexpected absence during a given three months interval after entry.²⁵ About 0.9% of job seekers are affected by ten or more workdays of caseworker absence per three-months period. Importantly, the largest share of the

²⁰The median caseworker-day cell has two meetings.

 $^{^{21}}$ I ignore the rare cases in which a caseworker does not return within 90 days, as these most likely reflect special circumstances.

²²In Switzerland, there are about 255 workdays per year and about 25 vacation days.

²³Holidays and vacations are not counted as absences.

 $^{^{24}}$ An absence needs to start during period t to be included into the job seeker's treatment status in t.

²⁵There are slightly fewer days of absence in months 1-3, as I do not count absences occurring during the first week after unemployment entry.

variation in the exposure to absences comes from within-caseworker variation. This ensures that there exists enough variation to estimate models with caseworker fixed effects.

[Insert Figure 3 and Table 2]

2.3 Caseworker Absences and Unemployment Exit: Raw Data

As a purely descriptive exercise, figure 4 plots the unemployment exit hazard and survival rate over the first 520 days of unemployment.²⁶ The solid line includes job seekers whose caseworker is absent during at least ten workdays over the first three months after entry into unemployment (0.9%). To avoid that dynamic selection confounds the picture, this status is assigned regardless of whether the job seeker is still unemployed at the start of the absence (intention-to-treat). The dashed line includes all other job seekers in the sample.

The graphs reveal that the initial spike of the exit hazard is visibly less pronounced for job seekers with a caseworker absence (panel a). The survival rate in panel b shows that this decreased probability of early exit goes along with a rather persistent increase in the medium-run probability of surviving in unemployment. Motivated by this descriptive evidence, the following section presents a stylized conceptual framework linking caseworker absences to the exit from unemployment.

[Insert Figure 4]

3 Conceptual Framework

This section provides a simple conceptual discussion on the role of caseworkers in the job search process. In particular, I describe how the empirical strategy can inform about quantity versus quality effects of caseworker resources.

Setup I set up a largely stylized, single-period job search process, where worker i is unemployed at the beginning of the period and searches for jobs with the help of caseworker j. There is no reservation wage choice, and changes in the effort choice and job arrival rate only result from actions taken by the caseworker. This simplified setup is motivated by the empirical setting, which provides variation in the interaction with caseworkers while holding the rest of the job search environment constant.²⁷ The probability s_i that job seeker i finds a job at the end of the

 $^{^{26}520}$ days is the maximum potential benefit duration in the sample.

²⁷Schmieder and Trenkle (2016) set up a similar framework to study the motivation of caseworkers in distributing resources among job seekers. In their setting, the job seeker's effort choice is also influenced by benefit levels and caseworkers can choose to use their resources to counteract disincentives from benefit generosity.

period therefore writes as a function of resources $c_{j(i)}$ of caseworker j assigned to i, job seeker characteristics X_i and the calendar time of entry into unemployment τ :

$$s_i = \phi(c_{i(i)}, X_i, \tau) \tag{1}$$

Caseworker resources $c_{j(i)}$ are composed of the number m and productivity $q_j \sim \mathcal{N}(0, \sigma_q^2)$ of meetings with the caseworker:

$$c_{j(i)} = (1 + q_j)m = \begin{cases} (1 + q_j) m^0 & \text{if } A_{j(i)} = 0\\ (1 + \underline{\bar{q}}_{-j}) m^1; \ m^1 < m^0 & \text{if } A_{j(i)} = 1 \end{cases}$$
(2)

If caseworker j is present at work when assigned to i $(A_{j(i)} = 0)$, i is provided a fixed number of meetings.²⁸ The meeting quantity affects the job search process through two components: the caseworker-constant component m^0 contains the average content of a meeting, i.e., standard advice and information, but also the potential disutility associated with the obligation of going to a meeting.²⁹ The second component is the product between m^0 and an additive, caseworker-specific productivity term, $q_j \sim \mathcal{N}(0, \sigma_q^2)$. q_j measures whether a meeting with caseworker j is more or less productive than a meeting with the average caseworker in the office. Variation in q_j can, for instance, stem from differences in job matching skills, counseling techniques or the choice of program assignments.

If the caseworker is absent $(A_{j(i)} = 1)$, job seekers do not have any meeting with their assigned caseworker j. Instead, m^1 meetings take place with caseworkers who jump in for their absent colleague. As not all meetings are replaced due to transaction costs and capacity constraints, m^1 is lower than m^0 . In expectation, the replaced meetings have the productivity of the average caseworker present in the office, which is close to zero due to the distribution of q_i .³⁰

Therefore, the absence-induced change in allocated resources is composed of the meeting quantity differential, $m^1 - m^0$, and the loss of the caseworker-specific term m^0q_j . In the following, I discuss how heterogeneity in q_j can be used to reveal the relative importance of these two mechanisms. I do not exploit heterogeneity in replacement productivity, because whether and by whom a meeting is replaced may be endogenous to the job seeker's situation.

²⁸In reality, the number of meetings may vary with respect to job seeker characteristics. However, the absence-driven variation in meetings used in the empirical analysis does not depend on job seeker or caseworker characteristics.

²⁹If job seekers find it unpleasant to go to the PES and meet a caseworker, this disutiliy affects the value of being unemployed and potentially increases search effort.

unemployed and potentially increases search effort. 30 The empirical results confirm that the replacement productivity is on average zero and is unrelated to the absent caseworker's productivity. Nevertheless, some job seekers may receive caseworkers with a positive or negative additive productivity as an replacement. It is assumed that the effects of replacements are symmetric.

Implications for the Empirical Analysis First consider a log-linearized version of equation 1 after plugging in expression 2:

$$s_i = \alpha + \rho_i + \delta A_{i(i)} + X_i \beta + \lambda_\tau + \epsilon_i \tag{3}$$

The constant term α contains the average effect of meetings m^0 provided by caseworkers when present at work. ρ_j is the additive effect of caseworker j's productivity, i.e., the empirical equivalent of q_j .³¹

 δ measures the average effect of the absence $A_{j(i)}$. Following the above discussion, it contains two effects: (i) the quantity effect of a reduction in the number of meetings and (ii) the quality effect of a potential change in the meeting productivity. If there are an equal number of negative and positive productivity changes in the data, and if their effects are symmetric, (ii) is zero.

To learn about the relative importance of quantity versus quality effects, I decompose the effect of an absence according to the absent caseworker's productivity at work, ρ_i :

$$s_i = \alpha + \rho_j + \gamma_1 A_{j(i)} \times \mathbb{I}(\rho_j < 0) + \gamma_2 A_{j(i)} \times \mathbb{I}(\rho_j \approx 0) + \gamma_3 A_{j(i)} \times \mathbb{I}(\rho_j > 0) + X_i \beta + \lambda_\tau + \epsilon_i$$
(4)

In the above specification, $\hat{\gamma}_2$ measures the effect of an absence on job seekers whose case-worker has about zero additive productivity. This group experiences, on average, no change in the caseworker-specific meeting productivity, as the replacement has in expectation zero additive productivity as well. $\hat{\gamma}_2$ thus isolates the effect of a drop in the number of average caseworker meetings from m^0 to m^1 :

$$\hat{\gamma}_2 = E(s_i \mid m = m^1) - E(s_i \mid m = m^0)$$

In turn, $\hat{\gamma}_1$ and $\hat{\gamma}_3$ additionally contain the effect of loosing the caseworker-specific term $\rho_j m^0$. $\rho_j m^0$ can be positive or negative, depending on the caseworker's additive productivity.

$$\hat{\gamma}_1 = \hat{\gamma}_2 + E(s_i \mid \rho_i m^0 = 0) - E(s_i \mid \rho_i m^0 < 0)$$

$$\hat{\gamma}_3 = \hat{\gamma}_2 + E(s_i \mid \rho_i m^0 = 0) - E(s_i \mid \rho_i m^0 > 0)$$

If $\rho_j < 0$, the absence induces a gain in the caseworker-specific meeting productivity, as the absent caseworker is replaced by a more productive substitute. I therefore expect $\hat{\gamma}_1 > \hat{\gamma}_2$. If

³¹It is possible that the caseworker's effect on unemployment exit also results from actions taken outside of meetings (e.g., by written communication). These would also be captured by ρ_j .

4 Average Effects of Caseworker Absences

The following section estimates the average effect of caseworker absences, without taking into account heterogeneity in caseworker productivity. First, I set up the empirical model and discuss its identifying assumptions. I then present the estimated effects on the exit from unemployment and on the quantity of realized meetings, including a discussion of spillover effects on present colleagues.

4.1 Empirical Model

Estimation Equation (Intention-to-Treat) To estimate equation 3, I adapt it to the institutional framework and measurement of absences presented in section 2. The main variable of interest, $ABS_{j(i),t}$, contains the number of workdays during which caseworker j is absent over the three-months period t after job seeker i's entry. Outcomes y_i include the linear probability of exiting unemployment within a given period, the linear duration of unemployment in days and the number of realized caseworker meetings. I thus estimate the following equation using OLS:³²

$$y_{i} = \alpha + \rho_{j} + \delta_{1-3}ABS_{j(i),1-3} + \delta_{4-6}A_{j(i),4-6} + \lambda_{\tau} + X_{i}'\beta + \varepsilon_{i}$$

$$A_{j(i),t} \in \{ABS_{j(i),t}, \mathbb{1}(ABS_{j(i),t} \ge 10)\}$$
(5)

The coefficients of interest δ_t measure the effect of caseworker j's absence occurring in time period $t \in (1-3,4-6)$ after i's entry into unemployment. The focus is on absences in months 1-3 and 4-6 after entry, because job seekers are most intensely followed by their caseworker during these initial periods of the unemployment spell.³³ The treatment variable $A_{j(i),t}$ either includes the linear number of days during which caseworker j was absent in period t $(ABS_{j(i),t})$ or a binary variable which equals one if $ABS_{j(i),t}$ contains ten or more days $(\mathbbm{1}(ABS_{j(i),t} \geq 10))$.³⁴ As $ABS_{j(i),t}$ does not take into account whether job seeker i is still unemployed when the caseworker becomes absent, δ_t defines an intention-to-treat effect (ITT).

 ρ_j contains caseworker fixed effects. As discussed in section 3, ρ_j measures j's additive productivity during workplace presence. It further controls for all time-constant caseworker characteristics and addresses the threat that the caseworker's productivity while at work coincides with the likelihood of an absence. λ_{τ} contains fixed effects for the job seeker's calendar month

³²Results are robust to specifying the exit from unemployment as a proportional hazard (available upon request). Given the large number of estimated fixed effects, I refrain from estimating logit or probit regressions.

³³Later absences will mainly serve as placebo tests.

 $^{^{34}}$ Results will show that absences start mattering if they sum to at least ten days over a three-months period t.

of entry into unemployment. It controls for aggregate time shocks (e.g., health-related) which correlate both with the caseworker's probability of being absent and with the job seeker's labor market conditions. X_i features job seeker characteristics, whose summary statistics are reported in appendix table A.1.

Scaling to the Average Treatment Effect on the Treated In the above specification, δ_t estimates an intention-to-treat (ITT) effect of caseworker absences: the variable $ABS_{j(i),t}$ contains the number of caseworker absence days in period t after the job seeker's entry into unemployment. This measure does not take into account whether the job seeker is still unemployed when the caseworker becomes absent. In turn, the average treatment effect of on the treated (ATT) defines the effect of an absence on job seekers who are still unemployed and therefore actually experience the consequences of the absence. As a job seeker's survival in unemployment results from dynamic selection, the ATT cannot be estimated directly. I therefore instrument the actual treatment (the caseworker becomes absent in period t of the unemployment spell, and the job seeker is still unemployed at the first day of the absence) by the intended treatment (the caseworker becomes absent in period t after the job seeker's entry). Equivalently, this Wald estimator divides the ITT effects by the share of individuals who are unemployed at the first day of the absence. ³⁵ In the results section, I show both ITT and ATT results. In addition, I present effects of absences on the number of realized meetings, to interpret the effects on unemployment exit in terms of foregone caseworker interactions.

4.2 Identification

Equation 5 exploits variation in absences within caseworkers over time. Its identification relies on the assumption that the exact caseworker-specific timing of an absence is as good as random from the job seeker's perspective – conditional on aggregate time effects.³⁶ In the following, I discuss the validity of this strategy.

Composition of Job Seekers The identification strategy implies the assumption that caseworker absences do not respond to job seeker characteristics. This assumption holds if the timing of caseworker absences does not respond to the characteristics of assigned job seekers.

Table 3 tests whether a job seeker's exposure to caseworker absences is influenced by her predetermined characteristics. In panel A, the outcome is the number of days during which the job

³⁵The resulting ATT estimate represents a lower bound, as job seekers may exit unemployment during an absence and therefore be only partially affected.

³⁶The identification strategy is related to Mas and Moretti (2009), who study the effects of coworker (cashier) productivity using within-worker variation in the composition of coworkers over ten-minute intervals. Herrmann and Rockoff (2012), who study the effects of teacher absences on student test scores, use a similar approach, exploiting variation within teachers over school years.

seeker's caseworker is absent during months 1-3 and 4-6 after entry $(ABS_{j(i),t})$. In panel B, it is the linear probability that $ABS_{j(i),t}$ contains 10 or more workdays. In columns 1 and 4, no caseworkers fixed effects are included in the regression. The reported coefficients suggest that there is some selection of job seekers to frequently absent caseworkers. The selection may be due to spatial correlations between job seeker characteristics and PES-specific absence rates, or due to the endogenous assignment of frequently absent caseworkers to certain job seekers within PES offices. To test the relevance of these two mechanisms, columns 2 and 5 add PES fixed effects. These fully capture the selection effect. Within offices, frequently absent caseworkers are thus not systematically assigned to certain types of job seekers. After replacing PES fixed effects by caseworker fixed effects in columns 3 and 6, it remains that absences are unrelated to pre-determined characteristics. This supports the assumption that the caseworker-time specific variation in absences occurs independently of job seeker characteristics.³⁷

[Insert Table 3]

Caseworker Workload As a direct reflection of changes in the local unemployment rate, changes in workload could induce a non-causal relation between absences and unemployment exit. I test for the relationship between workload and absences by running regressions on the caseworker-month level. For each calendar month τ , I count the new cases assigned to each caseworker, as well as their share of the monthly PES-level inflow. I then assess whether the new workload received in month τ affects the incidence of absences in the following two three-months periods ($\tau + 1$ to $\tau + 3$ and $\tau + 4$ to $\tau + 6$).

In table 4, columns 1 and 3 report results from regressions without caseworker fixed effects. They show that absenteeism is unrelated to the overall PES-level inflow, but negatively correlated with the caseworker's share of this inflow. The correlation is most likely mechanical: caseworkers who are overall less present at work are assigned on average a lower share of the inflow. Indeed, the correlation disappears when caseworker fixed effects are included (columns 2 and 4), supporting the assumption that the caseworker-specific timing of an absence is not induced by workload.

[Insert Table 4]

Unobserved Caseworker-Time Trends: Placebo Test A remaining threat is that unobserved time-varying factors influence both caseworker absences and job seeker outcomes. To test

 $^{^{37}}$ One of the coefficients is marginally significant at the 10% level. Given the large number of estimated coefficients, this is likely attributable to chance.

for the existence of unobserved caseworker-time trends, future absences can serve as placebo variables in regressions on current outcomes. For instance, caseworker absences occurring in months 4-6, 7-9 and 10-12 after unemployment entry are placebo absences when regressing on an outcome which realizes within the first three months of unemployment.³⁸ Placebo tests will be shown in the next section, jointly with the main results.

4.3 Results

In the following, I first present effects of caseworker absences on the exit from unemployment. To interpret these effects in terms of foregone caseworker interactions, I then show the effects of absences on the quantity of realized meeting. In an additional analysis, I provide evidence that absent caseworkers exert negative spillover effects on their present colleagues.

Unemployment Exit To start, I analyze whether caseworker absence days affects the exit from unemployment in a linear way. To this end, figure 5 plots effects of the number of absence days occurring in months 1-3 of unemployment. Instead of the linear number of days $ABS_{j(i),t}$, the treatment variable used to estimate equation 5 contains five-days categories (e.g., 1-5 absence days, 6-10 absence days etc.). Outcomes are the probability to exit unemployment within six months (panel a) and the duration of unemployment in days (panel b).³⁹ For both outcomes, it appears clearly that absences influence the exit from unemployment if they accumulate to at least 10 days.⁴⁰ It is also visible that a linear specification of absence days would not match the observed effect pattern. In the following analysis, I thus use a binary treatment variable, which equals one if the job seeker's caseworker is absent during at least ten workdays over the three month window t after entry. Appendix table A.2 additionally presents coefficients of the linear variable $ABS_{j(i),t}$.

[Insert Figure 5]

Figure 6 reports the short and medium run effect of being affected by a caseworker absence which accumulates to ten or more days over a three-months period. In particular, the figure shows how the main effects and placebo estimates (effects of future absences on current outcomes) react to the introduction of caseworker fixed effects and individual covariates. Outcomes are the probability to exit from unemployment within T=3 and T=6 months. The x-axis denotes the

 $^{^{38}}$ The idea to use future workplace presence/absence as a placebo for current outcomes is taken from Mas and Moretti (2009) and Herrmann and Rockoff (2012).

³⁹I cap unemployment spells at 520 days because this is the maximum potential UI benefit duration in the estimation sample. 12.3% of observations are affected by the cap, as job seekers are not automatically de-registered after benefit exhaustion.

 $^{^{40}}$ As 92% of job seekers are still unemployed at the first day of absence occurring in the first three months after entry, ATT effects are very close to ITT effects.

three-months periods in which the absences occurred; the y-axis shows the size of the estimated coefficient. As described in section 4.2, ATT effects scale ITT effects by the share of job seekers still unemployed at the first day of a caseworker absence. The share of job seekers still unemployed at the first day of caseworker absence is 0.92 for t=1-3 and 0.67 for t=4-6.

Panels a and b present estimates from regressions without caseworker fixed effects and covariates. Clearly, these estimates appear to be biased, as estimated placebo effects of absences occurring after the outcome period are negative and statistically significant. This suggests a negative correlation between the caseworker's general absence probability and productivity at work. Panels c and d show that caseworker fixed effects are able to address this relation, as placebo estimates turn zero. Results remain statistically unchanged after the inclusion of covariates in panels e and f.

Table 5 reports the corresponding effects of the preferred specification with fixed effects and covariates. Panel A presents the ITT effects and Panel B the scaled ATT effects. Panel B of column 1 shows that an absence of ten or more days in months 1-3 decreases the probability to exit within three months by 2.4 percentage points, corresponding to a decrease of 8% relative to the mean. The probability to exit within six months decreases by 2.8 percentage points in response to both absences in months 1-3 and absences in months 4-6 (5\% relative to the mean, panel B of column 2). Column 3 reports no significant effect of early absences on the probability to exit within 12 months, suggesting that job seekers with early caseworker absences catch up later in the spell. As shown in column 4, absences in months 1-3 increase the duration of unemployment by 10 days (5% relative to the mean). Absences of months 4-6 show no significant effect on the duration of unemployment, suggesting that caseworkers matter mostly at early stages of the unemployment spell. This intuition is in line with evidence showing that early policy interventions in UI can have large effects. For instance, Black et al. (2003) find that early announcements of re-employment services exert a substantial threat effect on newly unemployed individuals. Similarly, Bolhaar et al. (2016) show that steering the initial search effort of Dutch welfare recipients increases early exits from unemployment.

Appendix table A.3 documents that the main estimates are invariant to several modifications of sampling choices and variable specifications.

[Insert Table 5]

As an additional analysis, I test in table 6 whether the effects differ by observed job seeker characteristics. The table directly presents ATT estimates of absences during months 1-3 of unemployment. It shows a low degree of heterogeneity in the effects. Very early reactions (effects on the exit within three months, columns 1 to 4) are significantly more pronounced among women and individuals with a previous income below the median. This is in line with the literature on active

labor market programs, which typically finds stronger reactions for women and individuals of low income potential (Card et al., 2010, 2015). However, columns 5 to 8 show that the heterogeneity fades out over the six months outcome window. It appears that in the medium run, all types of job seekers benefit from the interaction with a caseworker.

[Insert Table 6]

Meeting Quantity To interpret presented effects in terms of foregone caseworker interactions, table 7 reports effects on the number of meetings realized over the first T = 3/T = 6 months of unemployment. The number of meetings is normalized by the time spent in unemployment over period T.⁴¹ Figure 7 illustrates the effects and additionally presents placebo estimates. To relate to the presented effects on unemployment exit, I focus directly on absences which sum to 10 days or more over three months. Linear effects are shown in appendix table A.4.

Columns 1 and 2 of table 7 report estimated effects on the number of meetings realized between the job seeker and her assigned caseworker. As expected, this outcome decreases in response to caseworker absences. Absences of at least ten days during months 1-3 of unemployment induce on average a decrease of 0.62 meetings over the first three months and of 1.12 meetings over the first six months (ATTs). For both outcome windows, this corresponds to a decrease of about 40% relative to the mean. Absences in months 4-6 induce a drop of 0.56 meetings over the first six months (25 % relative to the mean). Given that the previously presented effects on unemployment exit were driven by absences in months 1-3, I conclude that job seekers who loose one caseworker meeting (or 40% of the average meeting quantity) over the first six months of unemployment stay unemployed 10 days longer. In interpret this estimate as a local effect, as it is likely that caseworker meetings have decreasing marginal returns.

It is a priori unclear whether job seekers affected by absences have *overall* less caseworker meetings. If there was perfect replacement, the total number of meetings should hardly react to absences. Therefore, columns 3 to 6 decompose the effect into an increased number of replaced meetings and a reduced total number of meetings. Results show that about half of the reduction in meetings caused by absences in months 1-3 is compensated by replacements (columns 3 and

⁴¹I.e., I multiply the number of meetings realized during period T by the share of days the job seeker remained unemployed during T. This normalization addresses the concern that the negative effect of absences on unemployment exit translates into a mechanical positive effect on the number of meetings, as job seekers have more meetings when they are unemployed longer. Results hardly differ when not applying the normalization (available upon request).

⁴²The fact that the effect is larger for the six months outcome window can have two reasons: on the one hand, the caseworker's absence can reach into months 4-6 if it starts in months 1-3 of the spell. On the other hand, caseworkers returning after an absence may need time to catch up on their meetings.

⁴³There is no exclusion restriction that allows testing whether meetings realized during months 1-3 or during months 4-6 drive this effect, as absences in months 1-3 affect the meeting quantity in both time windows.

4).⁴⁴ The other half translates into a reduction in the total number of meetings (columns 5 and 6). Column 4 shows that only one third of meetings foregone due to absences in months 4-6 are replaced. This suggests that meetings later in the spell are less prioritized by the PES and therefore less likely to be replaced. Altogether, the existence of replacement suggests that the estimated cost of loosing a meeting with the assigned caseworker is a lower bound to its costs in contexts without replacement mechanisms.

Figure 7 reports that placebo estimates on the effects of future absences on current meetings are equal or close to zero, suggesting the absence of any major confounding trend.⁴⁵

[Insert Table 7 and Figure 7]

Spillover Effects on the Performance of Present Caseworkers A caseworker's absence may also affect the performance of present colleagues in the office. The direction of spillover effects from caseworker absences is ex ante ambiguous: on the one hand, job seekers with an absent caseworker search less and decrease the competition for available vacancies in the local labor market (Crépon et al., 2013; Lalive et al., 2015).⁴⁶ This is expected to cause positive spillover effects on the exit probability of job seekers with present caseworkers. On the other hand, absent caseworkers temporarily increase the workload of their colleagues, who have to jump in as replacements. Therefore, all job seekers potentially receive less attention from their caseworker. From this second mechanism, I expect negative spillover effects.

Table 8 presents spillover effects of caseworker absences. For each job seeker i, I measure the percentage of job seekers who are affected by an absence of ten or more days during months 1-3 after entry, among individuals who enter the same PES office in the same calendar quarter as i, and who are not assigned to the same caseworker as i (leave-out mean). I estimate the effects of this office-specific absence rate conditional on caseworker and calendar month fixed effects, assuming that the exact time-PES specific variation in the absence rate is quasi-random from the job seeker's perspective.

To start, columns 1 to 3 assess whether there are spillover effects of caseworker absences on the number of meetings realized over the first six months of unemployment. Such effects occur if present caseworkers have to replace their absent colleagues and can therefore meet their own cases less frequently. Indeed, column 1 shows that when ten percent of job seekers in the office

 $^{^{44}}$ Replaced meetings are defined as meetings that take place with a different caseworker than the initially assigned one.

⁴⁵Placebo effects on the number replaced meetings over 6 months are marginally significant and negative (Figure 7d). These effects are however economically very small and work into the opposite direction as the main effects, which contain an increase in the number of replaced meetings.

⁴⁶Crépon et al. (2013) show that job search assistance decreases job finding rates among non-treated individuals. Lalive et al. (2015) find that an extension in the potential benefit duration increases job finding rates among unaffected individuals.

are affected by a caseworker absence, the job seekers counseled by other caseworkers in that office experience, on average, a reduction of .1 meetings with their caseworker over the first six months of unemployment. As expected, there are no spillover effects on the number of replaced meetings (column 2). The effect therefore translates directly into a reduction in the total number of meetings (column 3). Columns 4 to 6 further show negative spillover effects on the exit from unemployment. When ten percent of job seekers in the office are affected by a caseworker absence, the other job seekers' probabilities to exit within three and six months both reduce by 1 percentage point. The duration of unemployment increases by 3.5 days. These effects appear large compared to the small effect on the meeting quantity. This may be due to side effects of spillovers on other activities in the office, such as the overall intensity of job search monitoring. Further, caseworkers may have less preparation time when their workload increases, implying a lower meeting quality.

Table 8 further suggests that the presented spillovers do not bias the main effect, which does not change significantly after introducing the office-level absence rate into the regression. However, the empirical setting does not allow for conclusions on job search externalities that may arise when changing the number of job seeker-caseworker interactions on a larger scale.

[Insert Table 8]

5 Effects by Caseworker Productivity

Having established the average effect of caseworker absences, I now analyze its heterogeneity with respect to caseworker productivity. As discussed in section 3, absences can cause both a reduction in the quantity of caseworker meetings and a change in the quality of realized meetings. Provided that all job seekers receive on average the same type of replacement, the quality effect depends on the absent caseworker's productivity at work. Therefore, heterogeneity in the effects by the absent caseworker's productivity can reveal the relative importance of quantity versus quality effects. In the following, I first set up the empirical model and then present results for different outcomes.

5.1 Empirical Model

Additive Caseworker Productivity I estimate additive caseworker productivity by means of fixed effects, in the spirit of the commonly used method to measure teacher value added (e.g., Chetty et al., 2014a,b). I consider medium-run unemployment exit as the relevant output,⁴⁷ and hold other input factors, such as working conditions, the local employment office's resources or

⁴⁷Medium-run exit is only one out of many dimensions through which caseworker productivity could me measured. However, as I analyze the effects of absences occurring during the first six months of unemployment, it appears the most relevant one in the context of this paper.

the job seeker's characteristics constant. To this end, I set up the following expression for s_i , job seeker i's linear probability to exit unemployment within six months:

$$s_i = \alpha_c + X_i' \beta_c + \kappa_{o \times g} + \theta_i + \varepsilon_i \tag{6}$$

The estimation is performed at the level of the canton c. Therefore, α_c includes a canton-specific constant term, and β_c measures canton-specific returns to individual covariates X_i .⁴⁸ $\kappa_{o\times q}$ contains interacted PES office \times calendar quarter fixed effects.⁴⁹ This ensures that caseworkers face the same workplace conditions, office policies and local labor market conditions. θ_j measures the parameter of interest, caseworker j's additive effect on the probability to exit within six months. As I am interested in the interaction between productivity at work and the effect of absences, I want to avoid that job seekers treated by an absence contribute to the estimated productivity θ_j (c.f. the intuition of a leave-out mean). Therefore, the regression is run without job seekers who are affected by at least ten days of caseworker absence in months 1-3 or 4-6 after entry (i.e., for whom $ABS_{j(i),1-3} \geq 10$ or $ABS_{j(i),4-6} \geq 10$).

The criteria for assigning job seekers to caseworkers are mostly regulated by the cantonal authorities. Running regressions at the cantonal level therefore has the advantage of controlling more flexibly for potential influences of observed job seeker characteristics in the assignment process. From anecdotal evidence, the assignment is most often based on caseworker availability. However, observed criteria included in X_i , such as the job seeker's occupation or education level, may also influence the assignment. Appendix figure A.1 shows the densities of estimated caseworker effects $\hat{\theta}_j$ from regressions with and without covariates X_i . As the shape and variance of the two distributions hardly differ, job seeker characteristics appear to have a minor influence on the productivity measure.⁵⁰

Effects of Caseworker Absences by Productivity Having estimated θ_j as a measure of the caseworker's additive productivity when present at work, I introduce it as a source of heterogeneity into the main equation. This results in the following empirical approximation of equation 4 in section 3:

$$y_{i} = \alpha + \rho_{j} + \sum_{k=1}^{3} \gamma_{k} (ABS_{j(i),1-3} \times Tk_{j}^{\hat{\theta}}) + \pi_{k} + \lambda_{\tau} + X_{i}'\beta + \varepsilon_{i}$$

$$A_{j(i),1-3} \in \{ABS_{j(i),1-3}, \mathbb{1}(ABS_{j(i),1-3} \ge 10)\}$$
(7)

 $[\]overline{^{48}X_i}$ includes the same covariates as in equation 3. Summary statistics are reported in Table A.1.

⁴⁹I use quarter instead of month fixed effects to avoid small cells in PES with low monthly inflow.

⁵⁰Also recall from section 4.2 (Table 3) that within PES offices, frequently absent caseworkers are not systematically assigned to certain types of job seekers. This supports the idea that there are no sophisticated assignment rules which carefully map job seeker characteristics to caseworkers.

The heterogeneity analysis focuses on absence days occurring in months 1-3 of the spell $(ABS_{j(i),1-3})$. Given that more productive caseworkers cause faster exits, the composition of job seekers who are unemployed at the time of the absence risks to vary with $\hat{\theta}_j$.⁵¹ In the first three months after entry, 92% of job seekers are still unemployed at the first day of an absence.⁵² Therefore, compositional changes are a minor issue for absences in months 1-3.

As in the previous analysis, $A_{j(i),1-3}$ either contains the linear number of absence days, $ABS_{j(i),1-3}$, or a dummy variable which equals one if $ABS_{j(i),1-3}$ contains ten or more days. $A_{j(i),1-3}$ is interacted with j's tercile $Tk_j^{\hat{\theta}}$ in the office-specific distribution of estimated caseworker productivity $\hat{\theta}_j$.⁵³

The equation further includes π_k , the baseline effect of having a caseworker in a given productivity tercile. π_k is needed in addition to caseworker fixed effects ρ_j because some caseworkers work in more than one office during the sample period (269 out of 2269). These caseworkers can have different ranks in different offices. As before, the specification further includes fixed effects for the calendar month of entry, λ_{τ} , and individual covariates, X_i .

5.2 Results

I first estimate how absences of caseworkers in the three productivity terciles affect the exit from unemployment, including a decomposition into different exit destinations. To ensure that the heterogeneous effects can be interpreted as pure quality effects, I show in a second step that absences of caseworkers in the three terciles equally reduce the meeting quantity, and that the productivity of the replacement is constant across terciles. In a final step, I explore whether the usage of active labor market programs explains the heterogeneous effects of absences and assess the role of caseworker tenure.

Unemployment Exit In line with the previous section, I pool individuals affected by ten or more days of absence over months 1-3 after entry into a binary treatment variable. Appendix table A.5 additionally reports linear effects, which show the same pattern in terms of heterogeneity.

Table 9 reports how the effect of absences on the exit from unemployment interacts with the absent caseworker's productivity tercile. Columns 1 and 2 show effects on the probability to exit within six months, estimated without and with covariates. Caseworkers in the second tercile are on average as productive as the replacement – provided that replacements are in expectation performed by the average caseworker in the office. Their absence should thus mostly induce a reduction in the quantity of meetings, due to imperfect replacement. Results show that absences

⁵¹For example, productive caseworker may in the medium run remain with less employable job seekers.

 $^{^{52}93\%}$ for caseworkers in T1 and T2, 90% for caseworkers in T3.

⁵³I.e., I classify caseworkers into terciles depending on their productivity rank within office cells.

of caseworkers ranking in the second tercile decrease the probability to exit within six months by 2.6 percentage points (column 2). This estimate is close to the average effect reported in the previous section and corresponds to a change of 5% relative to the group-specific mean. Absences of caseworkers in the lowest productivity tercile show no effect on the exit from unemployment. For job seekers assigned to one of these caseworkers, the absence-induced loss in meeting quantity appears to be offset by a gain in productivity due to the replacement by a better caseworker. On the contrary, absences of caseworkers in the third tercile induce a negative quality effect, as the replacement is less productive. This expresses in a significantly more negative effect on unemployment exit. For instance, the probability to exit within six months decreases by 6.4 percentage points if the absent caseworker ranks in the third tercile (9% relative to the groupspecific mean). Results further show that early absences of highly productive caseworkers have a persistent effect: twelve months after entry, the probability to exit is still lowered by 3.2 percentage points (column 3). In terms of the overall unemployment duration, absences induce an increase by 19 days for caseworkers ranking in the third tercile and by 12.5 days for caseworkers ranking in the second tercile (column 4).⁵⁴ Absences of caseworkers in the lowest tercile have no effect on the duration. Appendix table A.6 further decomposes the heterogeneity by quintiles. It shows that the positive productivity effect of absences is mostly driven by caseworkers in the lowest quintile. The negative productivity effect is equally driven by caseworkers in the upper two quintiles.

[Insert Table 9]

Exit Destinations From a policy perspective, it is of interest to decompose the presented effects into different exit destinations: do productive caseworkers foster the job seeker's own search effort, or do they rely on vacancy referrals? Do they generate sustainable job matches? To answer these questions, table 10 presents heterogeneous effects of caseworker absences on the probability to exit towards different destinations within six months.

In columns 1 and 2, the outcome is split into jobs that are found by the job seeker's own effort and jobs that are found through a vacancy referral.⁵⁵ Results show that the relative importance of high productivity caseworkers expresses primarily in job finding through the job seeker's own effort. These caseworkers thus appear to be successful in increasing and directing search.

Effects on job stability are reported in columns 3 and 4, where the outcome is split into stable and unstable job finding. A job match is coded as stable if the job seeker stays out of formal unemployment for at least 12 months after exit.⁵⁶ Absences of caseworkers in the third tercile

 $^{^{54}}$ Effects on the unemployment duration are not significantly different between the upper two terciles.

 $^{^{55}}$ This information is recorded in the UI data when job seekers de-register from unemployment.

 $^{^{56}}$ The data do not report additional dimensions of job quality, such as post-unemployment wages.

show the most negative effect on the propensity to find a stable job match. In turn, exits to unstable jobs react equally to absences of caseworkers in the second and third terciles. This implies that not only the absolute number, but also the share of stable job matches is higher among the most productive caseworkers. This is remarkable, as treatments commonly used in UI - in particular job search monitoring and sanctions- have been shown to lower post-unemployment job stability (e.g., Petrongolo, 2009). Finally, column 5 shows that exits to non-employment do not react to caseworker absences.

[Insert Table 10]

Quantity of Meetings and Productivity of Replacement The presented heterogeneities can only be interpreted as pure quality effects if absences of caseworkers in the three productivity terciles equally reduce the meeting quantity.⁵⁷ Further, the productivity of the replacement needs to be constant with respect to the absent caseworker's productivity.

Columns 1 to 2 of table 11 shows that in all three productivity terciles, absences lead to a loss of roughly one meeting with the assigned caseworker (ATTs in panel B).⁵⁸ It is therefore granted to conclude that the effect of one caseworker meeting on the exit from unemployment strongly depends on caseworker quality.

Columns 3 to 4 show that about half of caseworker meetings are replaced in all productivity terciles. Further, columns 5 to 6 report results from regressions in which the difference between a job seeker's replacement productivity and the average PES productivity is regressed on dummies for the absent caseworker's productivity tercile, conditional on PES fixed effects.⁵⁹ This regression only includes job seekers who are affected by an absence and who receive at least one replaced meeting during the outcome period. Therefore, the second tercile is the omitted baseline category. Results show clearly that there is no difference in replacement productivity between the three terciles. This holds for both outcome periods (three and six months after entry).

[Insert Table 11]

The Role of Treatment Assignments The strong heterogeneity in the effect of caseworker absences raises questions about the underlying channels. Interactions between caseworkers and

 $^{^{57}}$ As before, the number of meetings is normalized by each job seeker's duration of unemployment over the outcome period.

 $^{^{58}}$ Column 2 reports a slightly stronger effect on meetings with caseworkers in the third tercile for the six months outcome window (difference between γ_1 and γ_3 at the margin of statistical significance). However, the difference is economically too small to explain that absences of caseworkers in the third tercile increase unemployment by 20 days, while absences of caseworkers in the lowest tercile show no effect.

⁵⁹If a job seeker has more than one replacement during the outcome period, I use the average replacement productivity.

job seekers have mostly two components: first, they contain the unobserved counseling process, in which caseworkers motivate job seekers, generate pressure to actively search for work, provide information and give guidance. Second, caseworker meetings can result in observed outcomes, such as the assignment of active labor market programs, the referral of vacancies and the imposition of benefit sanctions due to job search monitoring. In the following, I analyze how the number of treatments assigned over the T=3/T=6 months of unemployment reacts to absences of caseworkers in the three productivity terciles. This can shed light on the importance of observed treatments versus unobserved counseling techniques in the caseworker production function. As in the previous analyses, estimations are based on equation 7 and the binary treatment variable equals one if the caseworker is absent during ten or more workdays in months 1-3 after unemployment entry.

Columns 1 and 2 of table 12 present estimated effects on the number of assigned training programs. These programs mostly include job search trainings or skill classes, such as computer or language courses. While there is a jointly significant negative effect of absences on this outcome, the effect does clearly not differ systematically by caseworker productivity. Columns 3 to 6 show that there is a joint negative effect of absences on the referral of vacancies and on the incidence of benefit sanctions. While it appears from eyeballing that the effects are stronger for absences of caseworkers in the third tercile (columns 3 and 5), the difference between the interaction terms is insignificant or at the margin to significance.⁶¹

Altogether, I cannot find any strong evidence that the use of labor market programs drives differences in caseworker productivity. As a consequence, the unobserved content of meetings appears to render the replacement of productive caseworkers difficult. This result is in line with Huber et al. (2017), who use mediation analysis to show that the success of tough caseworkers cannot be explained by program assignments. My findings further suggest that "being tough", as proxied by the use of sanctions, is not the only determinant of caseworker performance. A large literature has focused on evaluating labor market programs (c.f. the surveys by Card et al., 2010, 2015), finding mixed results. This paper suggests that the counseling style of caseworkers, which is unobserved in traditional data sources, may be a more important driver of early exits from unemployment.

[Insert Table 12]

The Role of Caseworker Tenure In a final analysis, I assess the role of task-specific human capital for the performance of caseworkers. Provided that tenure measures the specificity of

⁶⁰I normalize these outcomes in terms of unemployment duration, as previously done for the number of meetings. ⁶¹Further note that only 3.9% of all job seekers find a job through a vacancy referral within the first six months of unemployment (c.f. table 10, column 2.

human capital (c.f. Becker, 1962), the negative effect of absences is expected to increase with tenure if caseworker human capital is task-specific. The UI registers do not provide information on caseworker characteristics. I observe, however, the full population of caseworker-job seeker matches since January 2008 and can therefore construct proxies of tenure and experience.⁶²

Table 13 reports how the effects of early caseworker absences on unemployment exit interact with tenure. 63 For each caseworker \times calendar month cell, I measure tenure as the number of prior months since 2008 during which the caseworker was assigned to at least one job seeker (columns 1 and 3). As an alternative measure, I count for each caseworker \times calendar month cell the number of prior cases assigned since 2008 (columns 2 and 4). I then perform median splits within each month cell. 64

Results show that absences of more tenured and experienced caseworkers cause stronger reductions in unemployment exit (statistically significant difference in columns 1 and 4). It thus appears that caseworkers hold largely task-specific human capital, implying that their performance increases with experience on the job. As a consequence, more tenured caseworkers are harder to replace in the case of an absence. In line with this intuition, Lazear and Shaw (2008) show that worker productivity strongly increases with tenure. Further, Jäger (2016) finds that if is difficult for firms to replace a long-tenured worker after an exogenously caused job separation. ⁶⁵

[Insert Table 13]

6 Conclusion

This paper exploits exogenous variation in unexpected work absences to estimate how UI caseworkers affect the unemployment exit of job seekers. I find that job seekers are highly reactive to the presence of their caseworkers: reducing the amount of early caseworker interactions by 40% (\approx one meeting) increases the average duration of unemployment by 10 days. However, the average effect masks substantial heterogeneity, as it is entirely driven by the most productive caseworkers. For job seekers assigned to a caseworker with low productivity, the absence-induced loss in meeting quantity is fully offset by the gain from meeting a better caseworker as a replacement. Further, the negative effects of absences are driven caseworkers with high tenure and experience, suggesting lower replaceability of caseworkers with larger task-specific human capital.

The results suggest that investments into the human resources of welfare systems can have

 $^{^{62}\}mathrm{I}$ do not use the years 2008-2009 for the main analysis because the meeting data is incomplete prior to 2010.

 $^{^{63}}$ The table directly reports ATT effects. ITT effects are available upon request.

⁶⁴The same caseworker can thus have different levels of relative tenure and experience in different calendar months.

⁶⁵In addition, a large literature documents that job seniority increases wages and makes job separations more costly for workers (e.g., Topel, 1991).

high payoffs in terms of early exits from unemployment. On the quantity side, caseload reductions can increase the time spent on each job seeker. The spillover analysis showed that job seekers exit less quickly if their caseworker has to replace absent colleagues, confirming the economic relevance of caseloads. However, results also revealed that an increased quantity of job seeker-caseworker interactions will mostly pay off if their quality also improves, calling for investments into caseworker productivity. Such investments could target the selection of individuals attracted by the caseworker profession (e.g., through higher salaries of) or the skills of the existing stock of caseworkers (e.g., through training). Further, reducing the number of job separations among caseworkers may help increasing the amount of task-specific human capital. Lazear and Oyer (2013) review existing evidence on the determinants of productivity in firms, as offered by research in personnel economics. Future research is needed to understand which interventions and human resource practices work to increase caseworker performance in welfare and UI systems.

As a final policy implication, the findings of this paper show that workplace absenteeism may induce substantial costs. This holds in particular when the absent worker is difficult to replace due to high work productivity or high task-specific human capital. Commonly used investments into the reduction of work absences include preventive health interventions or the improvement of working conditions. The findings presented in this paper suggest that such investments may translate into important economic payoffs.

⁶⁶This study cannot inform about general equilibrium effects which could bound the positive effect of the interaction with caseworkers.

⁶⁷There is a small literature studying the selection of workers into the public service, mostly in the context of developing countries. For instance, Dal Bo et al. (2013) show that changes in posted salaries change the composition of applicants for public service jobs. Ashraf et al. (2016) find that agents attracted to the public service by career concerns have more skills and ambitions than those attracted by purely altruistic motives.

7 Figures

Figure 1: Share of Job Seekers who Meet their Initially Assigned Caseworker over Month of UE

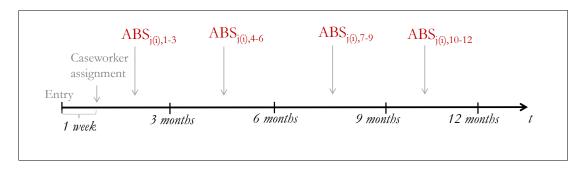

The figure displays the share of job seekers who meet their assigned caseworker in a given month after entry into unemployment. For each month, this fraction is computed based on the job seekers who are still unemployed at the end of that month.

Figure 2: Monthly Share of Caseworkers with Unexpected Absence

The figure shows the share of caseworkers who have at least one day of unexpected absence per calendar month. The measurement of unexpected absences based on unrealized caseworker meetings is described in section 2.2.

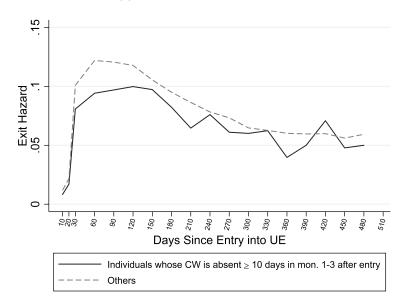

Figure 3: Timeline

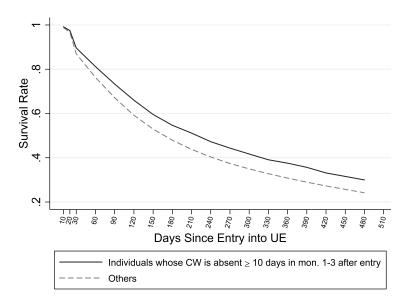

The figure illustrates the assignment of caseworker absences to the job seeker's unemployment spell. $ABS_{j(i),t}$ includes the cumulative number of days during which caseworker j is absent over a three-months period t of job seeker i's unemployment spell.

Figure 4: Caseworker Absences and Unemployment Exit: Raw Data

(a) Unemployment Exit Hazard

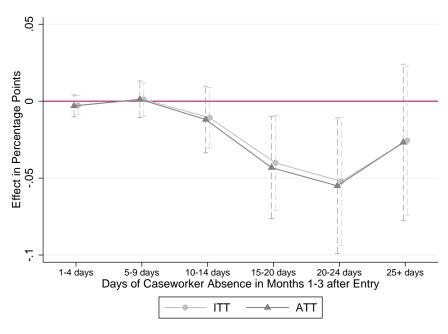

(b) Unemployment Survival Rate

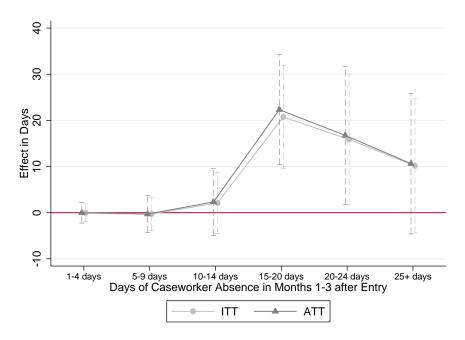

The unemployment exit hazard and the unemployment survival rate are computed over 10 day intervals during the first 30 days of unemployment and over 30 day intervals starting after day 30. The solid line refers to job seekers whose caseworker is absent during at least 10 workdays over the first three months after entry into unemployment (0.9%). This status is independent of whether the job seeker is still unemployed at the time of the absence (intention-to-treat). The dashed line refers to all other job seekers. N=382123.

Figure 5: Effect of Caseworker Absences in Months 1-3 on the Exit from Unemployment

(a) P(Exit within 6 Months)

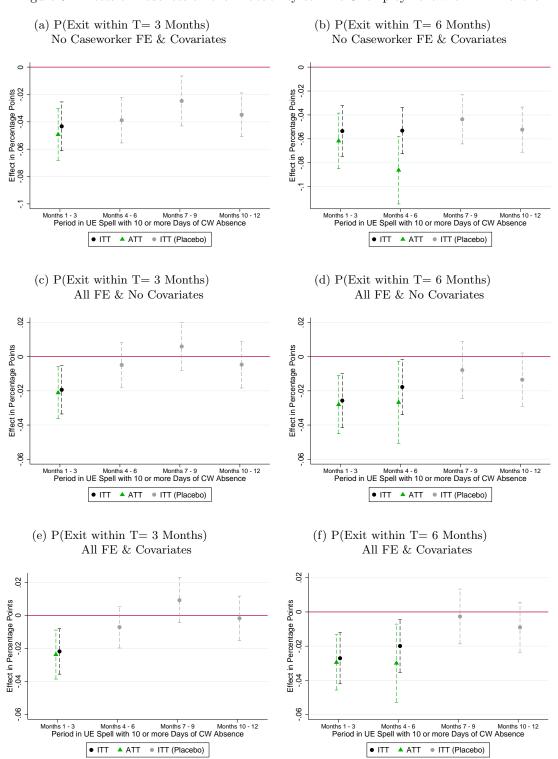

(b) Unemployment Duration in Days

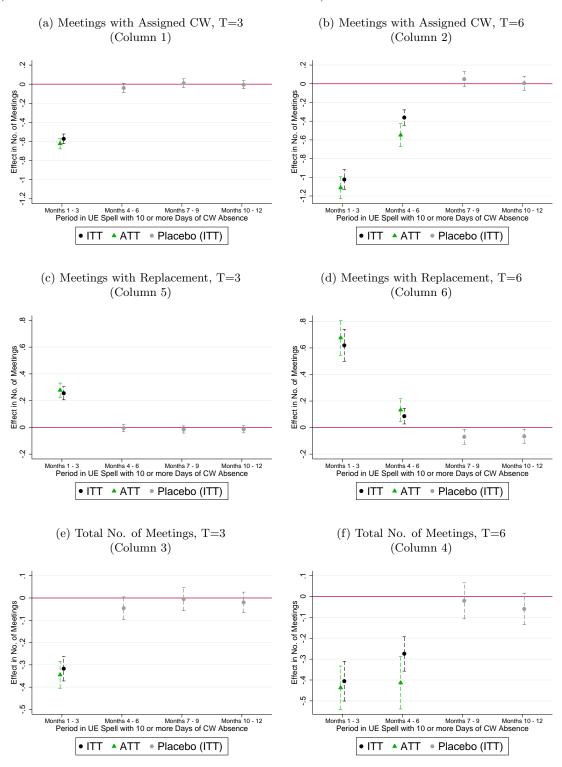

The figure plots the estimated effects of caseworker absences occurring within the first three months after entry. The x-axis denotes the cumulative number of days (in five day categories) during which the caseworker was absent in months 1-3 after the job seeker's entry into unemployment. The reference group contains job seekers with no caseworker absence during this period. The y-axis denotes the size of the estimated coefficient. In panel (a), the outcome is the linear probability of exiting unemployment within six months. In panel (b), the outcome is the linear duration of unemployment in days (capped at 520 days for 12.3% of the sample). Regressions include fixed effects for the job seeker's calendar month of entry into unemployment, caseworker fixed effects and covariates (c.f. equation 3). ATT estimates scale ITT estimates by the share of job seekers still unemployed at the first day of absence (0.92). Dashed lines represent 90% confidence intervals. Further estimation details can be found in section 4. N=382123.

Figure 6: Effects of Absences on the Probability to Exit Unemployment within T Months

The figure illustrates estimated effects of absences, based on equation 3. The regressions also estimate placebo effects of absences occurring beyond the outcome window. The treatment variable equals one if the job seeker's caseworker was absent during 10 or more days in the three-months period t after unemployment entry. In panels a and b, fixed effects and covariates are excluded. Panels c and d add fixed effects and panels e and f add covariates. Effects shown in e and f are also reported in columns 1 and 2 of table 5. The x-axis denotes the three-months period in which the caseworker absence occurred. The y-axis denotes the size of the estimated coefficient. ATT estimates scale ITT estimates by the share of job seekers who are still unemployed at the first day of absence (0.92 for t=1-3, 0.67 for t=4-6). Dashed lines represent 90% confidence intervals. N=382123.

Figure 7: Effects of Caseworker Absences on the Number of Meetings Realized Within T Months (Illustration of Results from Table 7 and Placebo Tests)

The figure illustrates estimates reported in table 7. It further reports estimated placebo effects of absences occurring beyond the outcome window. The treatment variable equals one if the job seeker's caseworker was absent during 10 or more days in the three-months period t after unemployment entry. The x-axis denotes the three-months period in which the caseworker absence occurred. The y-axis denotes the size of the estimated coefficient. ATT estimates scale ITT estimates by the share of job seekers who are still unemployed at the first day of absence (0.92 for t=1-3, 0.67 for t=4-6). Dashed lines represent 90% confidence intervals. Further estimation details are included in the notes of table 7. N=382123.

8 Tables

Table 1: Summary Statistics on Unexpected Caseworker Absences: Caseworker Level

	Mean	SD	N
Total workdays during sample period	874.450	394.048	2269
Workdays absent during sample period	20.856	19.960	2269
Ratio of absent over total workdays	0.023	0.024	2269

Summary statistics are at the level of the caseworker. The sample covers job seeker inflows between 2010 and 2012. Workdays are the number of days during which caseworkers schedules meetings with job seekers in the sample. The measurement of unexpected absences based on unrealized caseworker meetings is described in section 2.2.

Table 2: Summary Statistics on Unexpected Caseworker (CW) Absences: Job Seeker Level

		Time Period after Entry into UE				
		Months 1-3	Months 4-6	Months 7-9	Months 10-12	
Workdays with CW absence						
	Mean	0.409	0.474	0.463	0.491	
	SD	1.870	2.035	2.044	2.197

	Mean	0.009	0.009	0.010	0.010	
	SD	0.093	0.097	0.097	0.102	
	SD between CW	0.041	0.045	0.042	0.044	
	SD within CW	0.086	0.090	0.091	0.095	
	N	382123	382123	382123	382123	

Summary statistics are at the level of the job seeker. The sample inflow period is 2010-2012. The measurement of unexpected absences is based on unrealized caseworker meetings, as described in section 2.2. The number of caseworker absence days in a given period is reported independently of the job seeker's exit from unemployment at the time of the absence. In months 1-3, the first week after entry is excluded to allow for updates in the assignment of job seekers to caseworkers.

In panel A, the outcome is the number of workdays during which the job seeker's caseworker is absent during months 1-3/4-6 after entry. In panel B, the outcome is the job seeker's linear probability that her caseworker is absent for at least ten workdays during months 1-3/4-6 after entry. Except for log previous earnings, all independent variables are specified as dummy variables. PBD=potential benefit duration. The unit of observation is the job seeker. In all columns, regressions include fixed effects for the calendar month of entry into unemployment. In columns 2 and 5, regressions also include PES office fixed effects. In columns 3 and 6, regressions also include caseworker fixed effects. *p < 0.10,** p < 0.05,*** p < 0.05,*** p < 0.01. Standard errors are clustered at the caseworker level (N=2269).

In panel A, the outcome is the number of workdays during which the job seeker's caseworker is absent during months $\tau+1$ to $\tau+3/\tau+4$ to $\tau+6$ after entry. In panel B, the outcome is the job seeker's linear probability that her caseworker is absent for at least ten workdays during months $\tau+1$ to $\tau+3/\tau+4$ to $\tau+6$ after entry. The number of new cases are the number of job seekers that enter in calendar month τ and are assigned to the caseworker. The share of the PES inflow is the ratio of the caseworker's new cases over the total number of new cases at the PES in τ . The unit of observation is the caseworker-month cell. In all columns, regressions include fixed effects for calendar month τ . In columns 2 and 4, regressions additionally include caseworker fixed effects. *p < 0.10,**p < 0.05,***p < 0.01. Standard errors are clustered at the caseworker level (N=2269).

Table 5: The Effect of Absences on Unemployment Exit within T Months

	P(Exit), T=3 (1)	P(Exit), T=6 (2)	P(Exit), T=12 (3)	UE Duration in Days (4)

N	382123	382123	382123	382123

 $ABS_{j(i),t} \geq 10$ equals one if job seeker i's caseworker j is absent during at least ten workdays in period t after the job seeker's entry into unemployment. T denotes the outcome period in months. Panel A reports ITT estimates based on equation 5. Panel B reports instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence (0.92 for t=1-3, 0.67 for t=4-6). The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). In column 4, the unemployment duration is capped if it lasts longer than 520 days (12.3% of the sample). *p < 0.10,** *p < 0.05,**** p < 0.01. Standard errors are clustered at the caseworker level (N=2269). Further estimation details can be found in section 4.

 $ABS_{j(i),1-3} \ge 10$ equals one if job seeker i's caseworker j is absent during at least ten workdays in months 1-3 after the job seeker's entry into unemployment. T denotes the outcome period in months. Regressions report instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence. ITT effects are available upon request. The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). "Low Education" equals one if the job seeker completed no more than the obligatory level of schooling. "Low Previous Earnings" equals one if the job seeker's pre-unemployment earnings were lower than the median. p < 0.10, p < 0.05, p < 0.05, p < 0.01. Standard errors are clustered at the caseworker level (N=2269). Further estimation details can be found in section 4.

 $ABS_{j(i),t} \ge 10$ equals one if job seeker i's caseworker j is absent during at least ten workdays in period t after the job seeker's entry into unemployment. T denotes the outcome period in months. The number of meetings is normalized by the duration of unemployment. To this end, the number of meetings realized during period T is multiplied by the share of days a job seeker was unemployed during T. Panel A reports ITT estimates based on equation 5. Panel B reports instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence (0.92 for t=1-3, 0.67 for t=4-6). The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). *p < 0.10,*** p < 0.05,**** p < 0.01. Standard errors are clustered at the caseworker level (N=2269). Further estimation details can be found in section 4.

Table 8: Spillover Effects of Absences

 $ABS_{j(i),t} \ge 10$ equals one if the job seeker's caseworker is absent during at least ten workdays in period t after the job seeker's entry into unemployment. For each job seeker i, "% $w/ABS_{j(i),1-3} \ge 10$ in PES" measures the percentage of job seekers for whom $ABS_{j(i),t} \ge 10$ equals one, who enter the same PES in the same calendar quarter as i and who are not assigned to the same caseworker as i (leave-out mean). The mean of this variable is 0.9%. T denotes the outcome period in months. The number of meetings is normalized by the duration of unemployment. To this end, the number of meetings realized during period T is multiplied by the share of days a job seeker was unemployed during T. Regressions estimate equation 5, adding the spillover variable. The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). In column 6, the unemployment duration is capped if it lasts longer than 520 days (12.3% of the sample). *p < 0.10, *p < 0.05, *p < 0.05, *p < 0.01. Standard errors are clustered at the caseworker level (N=2269). Further estimation details can be found in section 4.

 $ABS_{j(i),1-3} \geq 10$ equals one if the job seeker's caseworker is absent during at least ten workdays in months 1-3 after the job seeker's entry into unemployment. Tk equals one if the caseworker ranks in the k^{th} tercile of the office-specific productivity distribution. T denotes the outcome period in months. The number of assignments is normalized by the time spent in unemployment over T. To this end, the number of assignments realized during period T is multiplied by the share of days a job seeker was unemployed during T. Panel A reports ITT estimates based on equation 7. Panel B reports instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence (0.93 for caseworkers in T1 and T2, 0.90 for caseworkers in T3). The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). "Joint Sign." = test for joint significance of the three interaction terms. p < 0.10, p < 0.05, p < 0.05 Further estimation details can be found in section 5.

N	382123	382123	382123	382123

 $ABS_{j(i),1-3} \ge 10$ equals one if the job seeker's caseworker is absent during at least ten workdays in months 1-3 after the job seeker's entry into unemployment. For each caseworker \times calendar month cell, I measure tenure as the number of prior months during which the caseworker was matched to at least one job seeker since 2008 (columns 1 and 3). As an alternative measure, I count for each caseworker \times calendar month cell the cumulative number of prior cases assigned since 2008 (columns 2 and 4). I then perform median splits within each month cell. The same caseworker can thus have different levels of relative tenure and experience in different calendar months. T denotes the outcome period in months. Regressions report instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence. ITT effects are available upon request. The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). "Joint Sign." = test for joint significance of the two interaction terms. In columns 3 and 4, the unemployment duration is capped if it lasts longer than 520 days (12.3% of the sample). "p < 0.10," p < 0.05, "** p < 0.05, *** p < 0.01. Standard errors are clustered at the caseworker level (N=2269). Further estimation details can be found in section 5.

A Appendix (For Online Publication)

A.1 Additional Figures

Figure A.1: Kernel Density of Caseworker FE on P(Exit w/in 6 Months)

N=382123. The distribution is weighted by the number of job seekers per caseworker. Predictions are based on regression of caseworker fixed effects and interacted PES-calendar quarter effects on the job seeker's probability of exiting unemployment within six months (equation 6). The dashed line reports the density of estimated caseworker fixed effects predicted from a regression without job seeker covariates. The solid line reports the density of fixed effects predicted from a regression with covariates. Regressions is preformed at the cantonal level on job seekers who are unaffected by a caseworker absence of 10 or more days in the first or second three-month period of unemployment.

 $ABS_{j(i),t} \geq 10$ equals one if job seeker i's caseworker j is absent during at least ten workdays in period t after the job seeker's entry into unemployment. T denotes the outcome period in months. Panel A reports ITT estimates based on equation 5. Panel B reports instrumented ATT estimates, where the ITTs are scaled by the share of job seekers who are still unemployed at the first day of absence (0.92 for t = 1-3, 0.67 for t = 4-6). The unit of observation is the job seeker. All regressions include calendar month and caseworker fixed effects, as well as job seeker covariates (summary statistics reported in table A.1). Further estimation details can be found in section 4. In column 2, caseworkers who have less than 60 cases over the sample period are excluded (in the baseline specification, I exclude caseworkers with less than 30 cases). In column 3, all caseworkers are included. In column 4, job seekers affected by absences of 30 or more days during months 1-3 or 4-6 are excluded. In column 6, initially made caseworker assignments are not updated (in the baseline specification, I use updated assignments if the update occurs up to week 1 after the job seeker's entry). In column 6, updated assignments are used if the update occurs up to week 2 after the job seeker's entry. *p < 0.10, **p < 0.05, ***p < 0.01. Standard errors are clustered at the caseworker level (N=2269).
