

The third worker: Assessing the trade-off between employees and contractors*

Pedro S. Martins[†]

March 15, 2019

Abstract

Firms make labour demand decisions not only between open-ended and fixed-term employment contracts but also increasingly more between employees and contractors. Indeed, this 'third worker' format can be attractive for firms, particularly if employment law is restrictive. This paper examines empirically this potential trade-off drawing on a recent reform in Portugal that cut the severance pay of new employee hires while leaving unchanged the regulations affecting contractors. Our analysis draws on difference-in-differences methods and novel high-frequency firm-level panel data on both employees and contractors. We find that the lower severance pay had a large relative positive effect on the wage bills and worker counts of employees compared to contractors. This result, robust to a number of checks, highlights the role of labour regulations on employment levels, in general, and on more flexible work formats, in particular.

Keywords: Employment law, segmentation, severance, future of work.

JEL Codes: J23, J41, J63.

*The author thanks Maria Koumenta for suggestions, the Ministry of Employment, Portugal, for data access, and Graham Greene for the title. The author was Secretary of State of Employment in the Government of Portugal in 2011-2013 and was co-responsible for the reform evaluated in this paper.

1 Introduction

Most firms make a large number of labour demand decisions on a regular basis. These decisions have received considerable attention in academic and policy circles, particularly choices about the quantity of labour demanded or between permanent or fixed-term employment contracts (Booth et al. 2002, Blanchard & Landier 2002, Bentolila et al. 2012, Addison et al. 2014, Charlot et al. 2016). This paper examines a complementary, increasingly important, but far less researched decision: obtaining labour through employees or contractors (Abraham & Taylor 1996, Houseman 2001, Garen 2006, Dube & Kaplan 2010).

Indeed, (dependent or independent) contractors have seen their numbers increase over the last decade, in the context of the growth of international trade, outsourcing, and new technology, all factors with relevant effects in the organisation of firms. For instance, the percentage of workers in the U.S. engaged in alternative work arrangements, including contractors, rose from 10.1% in 2005 to 15.8 % in 2015 (Katz & Krueger 2016). In particular, the internet has thickened markets in a large number of services, lowering asymmetric information, facilitating the matching between buyers and sellers, and promoting more flexible labour arrangements. These developments have led to the emergence of the sometimes called ‘gig’, ‘on demand’, ‘platform’ or even ‘Uber’ economy, which raises a number of new questions (Trottman 2015) and proposals (Harris & Krueger 2015) regarding worker’s classification, tax collection, social security access, and product market competition.

In this paper, our focus is on a different potential driver of firm-level choices between employees and contractors other than those mentioned above: labour regulations (Lazear 1990, Besley & Burgess 2004, Boeri & Jimeno 2005, Martins 2009). These regulations cover a large number of aspects of labour relationships and vary considerably across countries and time (OECD 2014), leading to an ongoing debate about their effects and optimal policy. However, labour regulations critically apply only to employees, not to contractors, despite the fact that the actual differences in the labour delivered between the two formats can be very slim in many cases. Previous research, cited above, focused on the case of the U.S., highlighted the role of wages and benefits as a motivation for service contracts. However, it did not explicitly consider the role of employment protection, most likely because of the low levels of regulation in the U.S. labour market.

More specifically, in this paper we are the first to examine the potential trade-off between

employees and contractors in a causal context, in our case drawing on exogenous variation in employment protection legislation. In particular, we study the effects on employees (in contrast to the case of contractors) of a recent labour law reform in Portugal that reduced significantly the severance pay of (permanent and fixed-term) employees (Hopenhayn & Rogerson 1993, Ljungqvist 2002, Holzmann et al. 2011, Fella 2012, Boeri et al. 2016). At the margin, as severance pay is lower (and wage rigidities are pervasive), obtaining work through employment contracts may be relatively more profitable for firms than through service contracts if the two labour formats are indeed substitutable. Our analysis is based on a difference-in-differences approach, taking contractors as the counterfactual (control group) to employees (treatment group). The analysis is made possible by new high-frequency firm-level labour data that includes information on both employees and contractors (both their counts and their wage bills), in contrast to the in other data sets used in this still very small and so far U.S.-centred literature (Abraham et al. 2013).

The paper also contributes to the question on whether labour market regulations should be adjusted in a more systematic way along the business cycle (Martins 2016*c*). To the extent that one may conclude that severance pay reductions can serve as an important positive driver of employment levels, in particular in terms of employment contracts, during downturns, one may want to consider greater flexibility in severance levels over the business cycle. In this case, such flexibility could act as a counter-cyclical force to dampen employment fluctuations, in particular when traditional (or even non-traditional) macroeconomic policies are less effective. In this sense, this paper can also be regarded as a contribution to our understanding of the effects of severance pay on employment levels (Lazear 1990, Boeri et al. 2016).

In our results, we find significant evidence of a trade-off between the two types of labour, with large implicit elasticities of labour demand, of at least -1. This finding holds in a number of robustness checks, including a decomposition of the after and before periods - where we find a great overlap between the month when the new law came into force and the start of cumulative positive effects towards employment contracts -, different subsamples and a triple differences approach, considering the same relative periods three years before.

The structure of the remaining of the paper is as follows: the next Section presents the severance pay reform and provides some context on the labour market. Section 3 presents the social security data set used and a number of stylised facts about employees and contractors

and other descriptive statistics. The main results, both in terms of the wage bill and labour counts, are presented in Section 4, while Section 5 describes a number of robustness checks. Finally, Section 6 concludes.

2 The severance pay reform and its context

2.1 Labour institutions

As in several other countries, employment contracts in Portugal are subject to considerable legal protection against dismissal, in terms of severance pay, advance notice, grounds for dismissal (required motives), and dismissal procedures (in particular in dismissals for subjective or performance reasons). Moreover, legal uncertainty following a dismissal is also significant, including possible reinstatements (in case the dismissal is successfully challenged in court) or expensive settlements for firms, as indicated in the Portuguese labour code. In the latter dimension, fixed-term contracts may be seen as less expensive, as the maximum cost of a dismissal is bounded by the salaries payable until the contract expires. However, exceptions may apply if the contract is deemed permanent by an employment tribunal, for instance because the employer did not invoke valid reasons for a fixed-term appointment. Such differences in costs - together with the relatively large size in the country of seasonal or volatile sectors (such as tourism, construction or agriculture) and the low economic growth rates of the last years and resulting economic uncertainty - may explain the very large percentage of employees currently employed under FTCs in Portugal (22%), the third largest in the European Union (see Damas de Matos & Parent (2016) and the references therein for previous studies about FTC in Portugal).

In a similar vein, the general restrictions that apply to employment contracts may also serve as a driver of the growth of the number of contractors. Given that the latter are regarded as service providers, and not employees, they are not subject to employment law (or collective bargaining) and their contracts can be terminated at will, with no severance or advance notice, in stark contrast to the case of employees. Such far greater flexibility may represent a potentially profitable form of labour demand.

This motivation - reducing labour regulation costs - would complement the U.S. findings of Abraham & Taylor (1996) regarding firm's preferences towards contractors (in particular business support services) as driven by labour cost savings, output demand volatility, and skills

availability, all of which will also be applicable in the case of Portugal and other European countries. For instance, firms in Portugal do not pay social security taxes on contractors while they are subject to a 23.75% rate on total salaries in the case of employees. The labour regulation dimension would also complement the results of Houseman (2001), which highlights the importance of workload fluctuations and staff absences (although in a more general context of flexible staffing arrangements and not exclusively contractors). Moreover, Garen (2006) proposes the cost of measuring output and monitoring effort as an additional determinant of the choice of labour contract.

Given the increasing, even not necessarily representative, evidence of contractors delivering work very similar to that of employees, regulations have been introduced in Portugal as in other countries to distinguish more clearly the two work formats. In particular, the labour code (article 12) establishes four criteria to this effect: the work being conducted in an establishment owned by the firm that is paying for the service, the equipment used by the contractor being owned by the firm, the contractor following a timetable indicated by the firm, and the firm paying the contractor a fixed salary on a standard schedule. If two or more of the criteria above are considered as met in a given case by an employment tribunal, then the service provision contract may be converted into a (permanent) employment contract.

On the other hand, Social Security has also established penalties to firms that employ dependent contractors (5% of the payments made if over 80% of all the contractor's earnings come from the firm). Contractors (or their relatives) are also entitled to benefits in case of paternity, old age, sickness, disability or death, in exchange of a social security rate of approximately 20% applicable on their earnings from the second year as a contractor.

2.2 The severance pay reform

Following important macroeconomic imbalances, a gradual loss of competitiveness and large public sector deficits during the 2000s, in 2011 Portugal agreed with the European Union and the International Monetary Fund to implement an economic and financial adjustment programme (IMF 2011). In addition to several measures to promote fiscal consolidation and financial sector stability, the programme also established a number of structural reforms, including in the labour market. One such labour reform - examined in this paper - concerned a greater alignment of severance pay by European standards, from the then very high levels,

as set by the Labour Code.¹

More specifically, this law reform established that severance pay of new hires would be lowered from 36, 30 or 24 days per year (depending on whether the employment contract is fixed term or permanent and on its total duration, the latter if fixed term) to a new, common level of 20 days per year (independent of the type of employment contract). Moreover, new contracts would become subject to a maximum severance of 12 months while permanent contracts of new hires would no longer be subject to a minimum severance of three months applicable until then. In contrast, severance pay of employees hired before the new law would remain unchanged at the higher levels.²

It is important to underline that Portugal, as other eurozone countries, was subject at the time to high levels of binding wage floors, which can make adjustments in severance pay important for employment. For instance, in October 2011, approximately 12% of all private-sector employees were paid the national minimum wage. Moreover, a further 16.5% were paid the job-specific minimum wages established by collective agreements and government extensions, in both cases according to our calculations based on the ‘Quadros de Pessoal’ matched employer-employee census data set. Martins (2016*c*) and the references therein also highlight the very high level of (base) wage rigidity in Portugal, which reached unprecedented levels during the 2011-13 recession. In this context, severance pay may have negative employment effects, given the inability of firms to engage in bonding, i.e. reducing entry wages by the amount of future severance (Lazear 1990). Moreover, the high and increasing unemployment rates at that time made it very unlikely that pay of new hires would symmetrically increase in proportion to the reduction in severance. Indeed, in a companion paper we examine this specific question using a regression-discontinuity approach and two types of individual employee data and find no evidence of salary increases once the lower severance pay is in force (Martins 2016*b*).

The severance pay reform was delivered through Law 53/2011, which was submitted by

¹The Labour Code also establishes that severance pay can be increased but not decreased through collective or individual bargaining. See Hijzen & Martins (2016), Martins (2016*a*) and Martins (2016*c*) for evaluations of other labour market reforms implemented in Portugal between 2011 and 2013.

²Point 4.4 of the memorandum of understanding signed by the government with the ‘troika’ (EC, IMF and ECB) in April 2011 indicated that ‘The Government will submit by end-July 2011 legislation to Parliament to implement a reform in the severance payments for new hires [...]. Severance payments of open-ended contracts will be aligned with those of fixed-term contracts. The reform will re-design the system for severance payment entitlements as follows: total severance payments for new open-ended contracts will be reduced from 30 to 20 days per year of tenure with a cap of 12 months and elimination of the 3 months of pay irrespective of tenure; total severance payments for fixed-term contracts will be reduced from 36 to 20 days per year of tenure for contracts shorter than 6 months and from 24 to 20 days for longer contracts [...]’.

the government to parliament in July 2011 and published in October. This law, which came into force in November 1st, 2011, established as agreed in the memorandum of understanding described above that the severance applicable to all new hires from November would be of 20 days per year of tenure for all employment contracts (permanent or fixed-term). Moreover, severance was now subject to a maximum severance of 12 months (a criterion thus only binding after 18 years of employment) and no minimum severance, unlike for permanent contracts started before.³

The effectiveness or take up of the reform is likely to have been very high. In fact, the reform received widespread attention in the media, given that it was one of the first laws of the new government that had come into office in June and of the adjustment programme. Revisions to labour law typically attract considerable public attention, given their potential effects amongst a large share of the population and the relatively polarised views in the public media about these matters. Moreover, the new law, while still in its draft version, was discussed with union and employer confederations, both by the government and the parliament. These confederations, in particular on the employer side, disseminated the provisions of the law widely across employers, especially those affiliated in their associations. Indeed, the reform represented a significant reduction of total (employee) labour costs, of approximately 2.4% (10 days out of 14 months of salary per year, excluding other items such as social security, insurance, paid holidays and training costs). In some cases, this percentage could be even higher, given the more significant cut in severance for longer fixed-term contracts (16 days, corresponding to 3.8%) and the elimination of the minimum severance of three months for permanent contracts (70 days - from 90 to 20 -, corresponding to a 16.6% reduction in labour costs in the case of the termination of a one-year-long permanent contract).

To the extent that employees and contractors are substitutable by firms, we expect that the reduction in severance costs delivered by the law reform will lead to a relative increase in the employment and wage bills of the former compared to the latter. Considerable anecdotal evidence indeed points to such substitutability, given the many instances of individuals purportedly performing jobs that are also carried out by employees, sometimes even in the same firm or in the same establishment. The next sections present our empirical analysis of this

³Point 4.4 of the memorandum also established an ‘employers financed fund’ which was only implemented later. Additional changes in severance pay were then introduced in 2012 and 2013, namely to 18 and 12 days per year of tenure, depending on when the contract was made. These subsequent changes are outside the scope of this paper.

question.

3 Data and descriptive statistics

The data set used in this paper reports monthly social security information covering the entire population of firms in Portugal between January 2007 and June 2012. These data, made available by the Social Security Agency of the Ministry of Labour, are of high quality as they are used in the processing of social security payments, typically 34.75% of the salary of each employee (see Martins (2014) for more information on the data set). Critically for our purposes, the records available indicate the numbers of formal employees and service providers under contract by each firm in each month, as well as their wage bills (both of workers and contractors). The data set also includes additional variables such as the number of new hires and leavers (only in the case of employees, not service providers). An additional variable is the industry affiliation of the firm, according to an ISIC rev. 4 five-digit code. It is also important to note that the wage bill information in the data set includes severance payments (namely in the last month of the employment spell) and may be therefore lead to a small downward bias (in absolute terms) in our results, although only in the case of very short employment spells.

Before focusing on the sample we use in our main analysis, we present some statistics from the original data set, focusing on the year of 2011. In fact, we know of very little statistics on population or other representative data regarding the employees/contractors duality for Portugal or any other country. In total, we observe 426,711 firms in 2011, reporting a monthly average of 7.8 employees and 0.74 contractors each. Although potentially double-counting individuals, in particular contractors, who may be working for different at the same time, these statistics suggest that approximately 9% of workers are contractors, a figure consistent with the U.S. data (Katz & Krueger 2016). We also find that over half of all firms (236,202) report at least one contractor in at least one month during that year.

Turning to the wage information, the average individual monthly pay of employees is 713 euros while the equivalent figure for contractors is 1,003 euros. These two figures suggest a significant contractor gross wage premium, in contrast to the analysis of Dube & Kaplan (2010) in their study of janitors and guards. Our contractor gross wage premium could be reconciled with compensating differentials, as contractors face greater uncertainty in terms of job stability and are not entitled to employment law mandated benefits (paid holidays,

paid training, etc), or other explanations, including human capital, hours of work or employer taxes differences (the latter much lower in the case of contractors). On the other hand, the results hold against simple composition checks: Across firms (and months) which employ at least one employee, the average share of the wage bill of contractors in the total wage bill of the firm is 16.3%.

Interestingly, we also find a relatively strong correlation (61.4%) between the inter-industry (gross) wage differentials of employees and contractors. This finding stems from the estimation of simple wage equations separately for employees and contractors firm-level wage bills, including industry dummy variables and subsequently comparing their coefficients (results available upon request). We also find evidence of greater within-firm dispersion in employees count compared to contractors count. In fact, the coefficients of variation of the number of employees are always greater than those regarding the number of contractors, sometimes by a factor of two, even when excluding firms that do not report contractors in any month (results available upon request). This finding underlines the point made earlier about significant similarities between the jobs performed by employees and contractors: the latter are not necessarily hired only for one-off, short spells, following temporary needs by firms.

Our main analysis focus on the period 2011:m1 to 2012:m6, i.e. from ten months before the new law was in force until eight months when the new law was in force. The second part of this period excludes the months since the introduction of a second new law (in August 2012) that reduced severance levels further, in this case both for existing workers and new hires. Moreover, in our main analysis, we consider only firms that report contractors in at least nine months (of the 18 months covered in our sample) and that hire employees also in at least nine months. The first restriction is intended to ensure that contractors may be a potential significant margin of labour choices. In fact, if a firm never or almost never employs a contractor, it is unlikely that a trade-off can be discerned, other than through an extensive margin unlikely to be observed over the relatively short ‘after’ period observed. The second restriction (on worker turnover) is imposed to ensure that our analysis can focus on firms which may be affected by the lower severance levels. As indicated above, the reform was only applicable to new hires implying that firms with a very stable workforce will not be affected by the reform, once again leaving aside extensive margin considerations.

Table 1 presents descriptive statistics on the sample used in the paper. This sample

corresponds to a total of 145,892 firm-month-work type observations (and 4,081 different firms). This follows from our reshaping of the data set into two observations per firm per month, one corresponding to employees, the other contractors, in a given firm and month. We find an average number of workers (across employees and contractors) of 71,5 and an average wagebill (again across employees and contractors) of 91.235 euros. As we indicate below, as data on hours of work is not available for employees and cannot be measured in most cases for contractors, our results focus on the wage bill of each type of labour. Given our data construction method, half of the observations correspond to employee data, while 44% of the observations correspond to November 2011 and subsequent months.

The average number of employees per firm is 141 and the average monthly salary of each employee is 887 euros: as one would expect, our sample selection criteria directed us to large firms, paying average salaries. Average (monthly) worker flows ratio (hirings plus separations, divided by total employees) is 11%, a large figure that underlines the constant workforce reallocation work conducted in firms and paves the way for potential effects of the new law. We also report the logs of the key outcomes (workers and wage bill), including following an adjustment to address missing observations (namely zeros in the stock of contractors). This adjustment was based on adding one to both the original numbers of workers (both types) and wage bills (also both types), zeros or positive numbers. Table 1 also presents the percentages of firms in the five most important one-letter sectors: manufacturing (20%), construction (18%), wholesale and retail (16%), hotels and restaurants (11%), and administrative services (9%).

Finally, we describe in Figure 1 the time profiles of the mean log pay for employees and contractors over the period January 2011 to June 2012. The comparison of the two time series indicates a parallel growth (i.e. similar trends) during the months of 2011, including the same seasonal spikes at June and July and then November and December. However, it is noteworthy, from this visual inspection of the data, that from January 2012 (i.e. only two months after the reform is in force), the time series of employees pay is more resilient than that of contractors. While contractor's mean pay per firm falls between January and May, with only a slight rebound in June, the employees' mean pay is stable or even increases during those six months. This figure corresponds to suggestive graphical evidence that the severance law reform may indeed have had a positive effect in terms of employees, compared

to contractors. In the next Section, we will examine this preliminary finding in greater detail, using econometric methods.

4 Results

Our analysis is based on a difference-in-differences approach, taking employees in each firms as our treatment group and contractors in the same firms as the control group. November 2011 to June 2012 is defined as the ‘after’ period, in contrast to the period between January and October (the ‘before’ period). Our dependent variables are the wage bills and worker counts of each group (employees and contractors). Moreover, we draw on the firm-level panel structure of our data set to contrast the two series, before and after the new law is introduced, within each given firm. In other words, we consider each firm’s contractor time-series profile as the counterfactual to the employee time series and evaluate the effect of the new severance law for employees from any systematic differences that coincide over the post-October 2011 period. While the number of employees and contractors per firm is certainly different, as shown in Section 3, to the extent that their relative shares are similar within firms over time in the absence of the reform any differences found in our analysis in the employee series from November 2011 can be attributed to the reform.

Specifically, we consider the following difference-in-differences equation:

$$Y_{it} = \beta_1 \text{Employees}_i + \beta_2 \text{PostOct2011}_t + \beta_3 \text{Employees}_i * \text{PostOct2011}_t + \alpha_i + \epsilon_{it} \quad (1)$$

The dependent variable considered, Y_i , is the log of the wage bill or number of workers in firm i and month t (either employees or contractors). Employees_i is a dummy variable equal to one is the dependent variable refers to employees (zero, if it refers to contractors). PostOct2011_t is a dummy variable equal to one if month t is from November 2011 onwards (when the lower severance pay was in force). Finally, the key regressor is $\text{Employees}_i * \text{PostOct2011}_t$, the interaction of the previous two dummies, highlighting the observations corresponding to employees in months when the new severance law was in force. The equation also controls for firm fixed effects (α_i). The coefficient of interest, β_3 , will indicate any systematic percentage differences in the outcome of interest (wage bills or numbers of workers) in the period post-October 2011 relatively to the period up to October 2011, when comparing

employees and contractors in the same firms.

Table 2 presents our main results, on the wage bill effects, including or not firm fixed effects and using non-adjusted or adjusted variables. Given the lack of hours of work information, we consider the wage bill to be a more comparable metric of labour quantities and focus our analysis on this variable. First, we find, as expected from the descriptive statistics, that the wage bills are much higher (approximately fourteen times) when considering employees compared to contractors. Second, we find somewhat mixed evidence across the four columns when comparing the November 2011-June 2012 period with the period immediately before. However, our preferred estimates, based on the adjusted wage bill, indicate a decline in the after period, which is consistent with the recession and increasing unemployment that the country was facing at that time. Finally, we find across the four specifications that the coefficient of the interaction effect is always significantly positive. This result indicates that the employees' wage bill in a given firm increases, on average, compared to the contractors' wage bill in the same given firm once the new severance law is in force. The magnitude of the effect varies significantly (by a factor of three) depending on the sample used (although not with the inclusion of firm fixed effects) - .039 vs .143, respectively. We interpret this as a consequence of the consideration of the zeros in the data (instances in which the wage bill drops to zero in this case). In particular, dropping these observations, as it is the case under the non-adjusted results, removes an extensive margin that proves to be an important source of variability in the data and in a difference-in-differences specification.

Table 3 presents the equivalent results but now on the number of workers. As before, we find significantly larger numbers of workers as employees (compared to contractors) - and larger equivalent coefficients compared to Table 2, consistent with the positive wage differentials in favour of contractors. Similarly to that previous table, we find significant negative coefficients on the after dummy, although in this case of a smaller magnitude. Finally, we again find evidence of significantly positive relative effects on employees (compared to contractors) once the reform is in force. In this case, the coefficients are more similar across the adjusted and non-adjusted variables, at .028 and .016, respectively.

It is difficult to quantify the implied elasticities from our results. In fact, different firms will have different patterns of employment spell durations and employment contract types (permanent or fixed term), which will lead to different reductions in their relevant labour

costs from the severance law reform. As indicated in Section 2, the reductions in labour costs could be as high as 16.6% in the extreme case of firms that appoint workers as permanent and then dismiss them by end of their first year (or even higher for shorter employment spells). In the more common cases, these reductions will range between 2.4% and 3.8%. These figures are of the same order of magnitude as the coefficients of the interaction dummies across different specifications, suggesting a labour demand elasticity of around -1. However, when considering the (adjusted) wage bill specifications, this elasticity will increase to around -3. This higher figure may reflect the downturn in the economy when the reform is introduced (GDP contracted by 1.3% in 2011 and 4% in 2012) and the likely greater sensitivity of labour demand to labour costs that follows, coupled with the very high flexibility in the (downward) adjustment of contractors' wages and employment. These results, including their large implied elasticities, are also consistent with Martins (2014), which finds evidence of a similar trade-off between employees and contractors but in the very different context of the extensions of collective agreements.

5 Robustness checks

In this section, we present the findings from a number of robustness checks. First, we decompose the time effects discussed above in the specific months of both the before and after periods. In other words, instead of an 'after' dummy variable and its interaction with the treatment dummy variable (employees), we include in our specification one dummy variable for each month and one interaction for each month and the treatment dummy. This allows us to trace the monthly effect of the new law and also check for potential cumulative effects. In fact, the gap between employees and contractors following the lowering of severance pay of new hires uncovered in Section 4 is likely to increase gradually amongst the medium- and high-worker turnover firms in our sample. This approach also serves to test the common trend assumption in difference-in-differences, namely that no significant differences across the two groups of workers should be observed in the run up to the intervention.

The extended difference-in-differences equation we estimate is therefore the following:

$$Y_{it} = \beta Employees_i + \sum_{m=2}^{18} \delta_m I(t = m) + \sum_{n=2}^{18} \theta_n I(t = n) * Employees_i + \alpha_i + \epsilon_{it}, \quad (2)$$

where the variables are the same as in equation 1, $I(t = m)$ being an indicator function denoting the dummy variables for the different months over the period 2011:m2 up to 2012:m6 (2011:m1 being the comparison month).

The results are presented in Table 4 and highlight the strong overlap between the introduction of the new law and the gap between the number of employees and contractors within the same firms. In fact, across the ten months before the new law only two are significant at 5%; on the other hand, across the eight months once the new law is in place, only one (December) is not significant at 5%. Moreover, there is evidence of an increasing trend in the magnitude of the coefficients, consistent with the cumulative effect discussed before, from .078 in November, to .117 in January, .249 in April and .321 in June. Almost all the latter coefficients are also significant at the 1% level. These findings are also consistent with the graphical evidence presented in Figure 1.

We now turn to potential differences across sectors, focusing on the five most important in our sample. Table 5 presents the results from our preferred specification, a wage bill analysis, using adjusted labour and including firm fixed effects. We find significant effects in all sectors except administrative services. The effects are larger in hotels and restaurants, followed by retail and manufacturing. The non-significant results in administrative services may be related to the greater relative importance of employees in that section, indicated by the large coefficient on their dummy variable (3.4, compared to coefficients between 2.5 and 2.9 in the other four sectors).

A third robustness check involves the analysis of different subsets of our main sample. In Table 6 we consider low-wage firms, defined as those that have a mean salary of employees over all months below the median of the full sample (759 euros), and high-flow firms, defined as those that have a mean ratio of employee hirings plus separations by total employees above the median of the full sample (7.7%). For instance, firms that tend to have higher levels of turnover may benefit more from the reform, as the lower severance pay levels were only applicable to new hires. They will most likely have a greater reliance on fixed-term contracts, for which changes in severance costs will be more directly relevant, resulting in a stronger effect on behaviour, namely hirings of employees and contractors. Overall, we find estimates supporting the robustness of the main results presented in Tables 2 and 3, indicating positive effects of the new law on both wage bills and labour. More specifically, we find evidence of

somewhat lower effects amongst low-wage firms (a wage bill coefficient of .135 compared to .143 in the main findings) and, as expected from the discussion above, higher effects amongst high-flow firms (a wage bill coefficient of .164).

Finally, we examine the possibility that our main results are picking up seasonal patterns or other similar effects in the labour choices of firms and workers regarding employee and contractor formats. For instance, the period when the new law is in force may coincide with a greater propensity for the use of employees compared to contractors. We do not know of any reasons why this hypothesis may apply here but examine this possibility in any case. In fact, if anything, we would expect the period of the new law to be associated to a greater propensity for contractors, given the deteriorating economic conditions over these months and their likely implications in terms of firms preferring more flexible labour formats in their possibly diminishing hirings.

Our analysis of this potential even if unlikely threat to identification is based on a triple-difference approach, in which we add a third period to our analysis: January 2008 up to June 2009. To the extent that the seasonal effects described above are similar in this time period (similarly characterised by deteriorating economic conditions, in this case following from the 2008 financial crisis) and in the main period of January 2011 to June 2012, the inclusion of this additional difference will reveal if the main results still hold or not after controlling for these more general seasonal effects.

Given the above, the triple-difference equation we consider is the following:

$$\begin{aligned}
Y_{it} = & \beta_1 Employees_i + \beta_2 PostOct2008/11_t + \beta_3 Employees_i * PostOct2008/11_t \\
& + \beta_4 2011/12_t + \beta_5 Employees_i * 2011/12_t + \beta_6 PostOct2008/11_t * 2011/12_t \quad (3) \\
& + \beta_7 Employees_i * PostOct2008/11_t * 2011/12_t + \alpha_i + \epsilon_{it}
\end{aligned}$$

The interpretation of the variables above is the same as in equation 1, *PostOct2008/11_t* being a dummy variable equal to one both for the period November 2011 to June 2012 and for the period November 2008 to June 2009. Moreover, *2011/12_t* is a dummy variable equal to one for the period 2011-12 (both the months range subject to the treatment - November 2011 to June 2012 - and the months range just before - January 2011 to October 2011). The equation also includes all pairs of interactions and the critical triple interaction whose coefficient (β_7) is the result of interest - it indicates the difference in the outcome of interest between the post-

and pre-October 2011 (2008) months, comparing employees to contractors, and the 2011-12 period against the 2008-09 period.

Table 7 presents the results, including all coefficients. Once again, we consider our main specification, based on (adjusted) wage bill and firm fixed effects. We find that the key coefficient (β_7), of the interaction of the three dummy variables is significantly positive, at .034. This result indicates that, compared to an equivalent period in 2008/9, there is a positive, additional wage bill effect for employees from November 2011 compared to contractors in the same firms. This finding lends additional support to a causal interpretation of our main results, stemming from the change in severance pay.

6 Conclusions

A number of forces such as international trade, technology, or outsourcing are shaping the future of work, including a greater role for other labour relationships than (permanent) employment contracts. In fact, the breadth of non-standard work is considerably large these days, including different margins than the much-discussed segmentation between permanent and fixed-term contracts.

This paper analysed the increasingly important but still little discussed potential trade-off between employees and contractors. Moreover, we focus on the role of labour market regulation and, in particular, severance pay, as a driver of contractors to the expense of employees. At the same time, we also contribute to analysis of the effects of severance pay upon employment. Critically from an identification perspective, our analysis draws on the exogenous variation in the severance levels of employment contracts at a time when no changes were introduced to service contracts. The results indicate significant evidence of a large relative increase in the wage bills and numbers of employees within firms over time, with elasticities of -1 or more.

Our results are the first to present causal evidence on the effects of employment protection law, in particular severance pay, on the employee/contractor trade-off. From a policy perspective, these findings indicate that reductions (not increases) in labour regulations may help to promote more standard forms of employment, which offer far greater protection to workers. This may be particularly the case in contexts in which the economy is under a recession and or regulations are relatively restrictive. In general, greater responsiveness of labour regulation

to the business cycle may help to reduce employment volatility and increase economic welfare.

Figure 1: Log pay for employees and contracts per month

Notes: Each line indicates the (mean) log pay for employees and contractors (top and bottom graph, respectively) over the period January 2011 (month 1) to June 2012 (month 18). The vertical red line denotes the month when the new severance law came into force. The vertical axis is interrupted at 8 (contractors) and resumes at 10 (employees), given the different magnitudes of the two series. Own calculations.

Table 1: Descriptive statistics, pooled data

	Mean	SD
Workers	71.50	388.94
Wage bill	91,234.71	724,932
Employees (dummy variable)	0.50	0.50
Post-Oct 2011	0.44	0.50
Post-Oct 2011 * Employees (dv)	0.22	0.42
Mean employees per firm (over time)	141.40	539.72
Mean employees' wage bill per firm (over time)	887.15	520.32
Mean worker flows ratio per firm (over time)	0.11	0.10
Log workers	2.15	2.02
Log wage bill	9.21	1.90
Log workers (adjusted)	2.41	1.77
Log wage bill (adjusted)	9.06	2.21
Manufacturing	0.20	0.40
Construction	0.18	0.38
Wholesale and retail	0.16	0.37
Hotels and restaurants	0.11	0.31
Administrative services	0.09	0.29
Observations	145,892	

Notes: Monthly data, covering the period from January 2011 until July 2012. Two observations per firm per month, one regarding employees, the other contractors. Workers denotes the number of individuals registered in the firm-month (either employees or contractors). Wage bill denotes the amount paid to all individuals in the relevant firm-month-worker type cell, in nominal euros. 'Employees (dv)' is a dummy variable indicating cells that refer to employees. 'Post-Oct 2011' is a dummy variable indicating cells that refer to the months of October 2011 and after. 'Mean employees (employees' wage bill) per firm' is a variable indicating the mean number of employees (employees' wage bill) in the firm (across all time periods). 'Mean worker flows ratio per firm' is constructed from the ratio of total employees hirings and separations in a month by that month's employees stock, averaged over all months. 'Log workers (wage bill)' is the log of the variables indicated above; the adjustment versions are again the same logs but first adding one to the numbers of workers or the value of the wage bill (to address the zero reported workers and wage bill in a small number of cases). The last five dummy variables refer to one-letter sectors. 143,555 observations for log workers and log wage bill.
